Lake Rummelsburg: a partly separated expansion of the river Spree in the urban area of Berlin

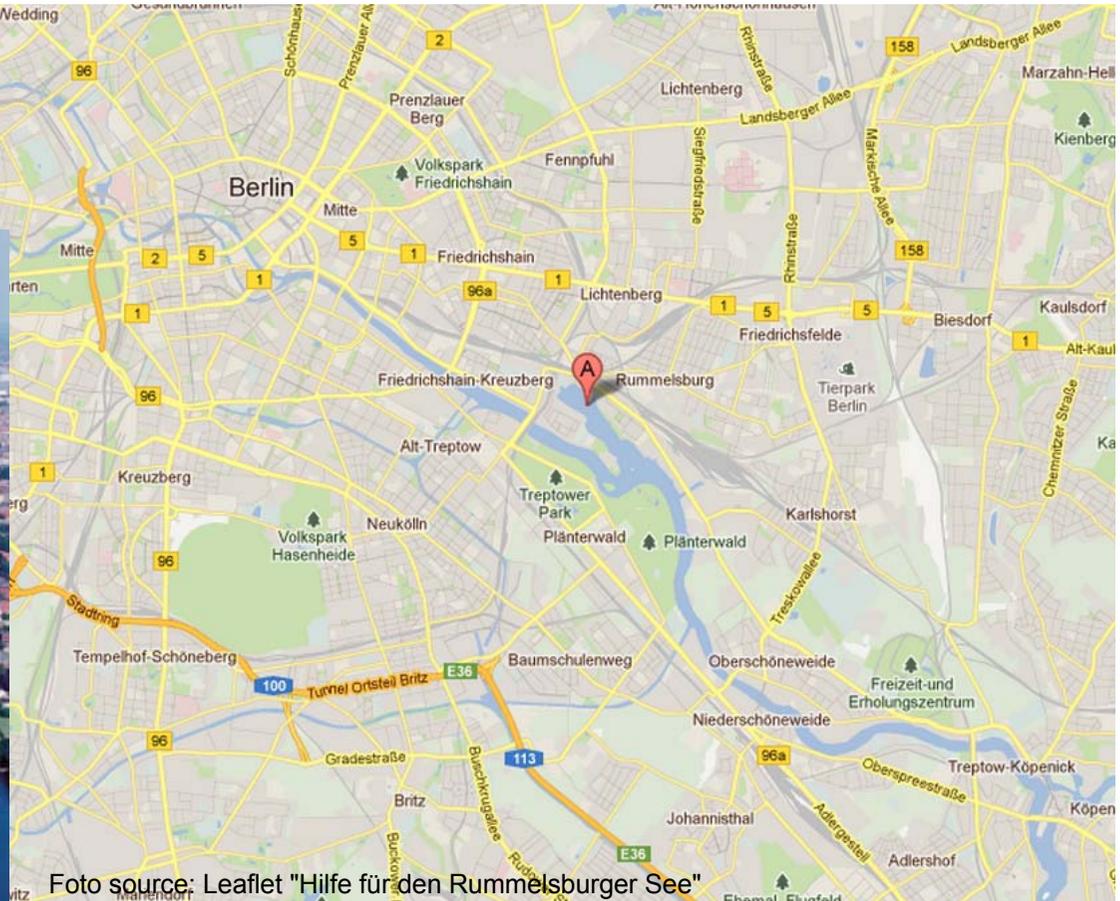

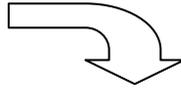

Foto source: Leaflet "Hilfe für den Rummelsburger See"
Senate Department for Urban Development and the Environment, Berlin

Hydrographical data

Lake surface	45 hectare
Largest extension	ca. 1,6 km
Width	ca. 0,3 km
Maximum water depth	ca. 4,8 m
Average water depth	ca. 2,5 m
Lake surface separated by a sheet pile	34 hectare

Changed claims of utilization

Since the 19th century mainly industrial use of the area around the lake
- asphalt-production, glass factory, galvanisation plant, old ships graveyard,
effluents from waste water treatment plant, rain water drainage channel

City-centre brownfield land since the 1990s

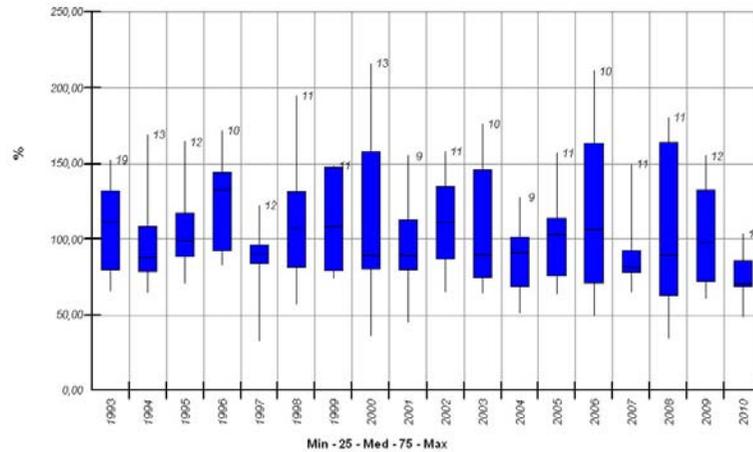

Reclassification as attractive services and residential area
with water connection

Changed claims: residential area, „floating lofts“, watersports, recreation area

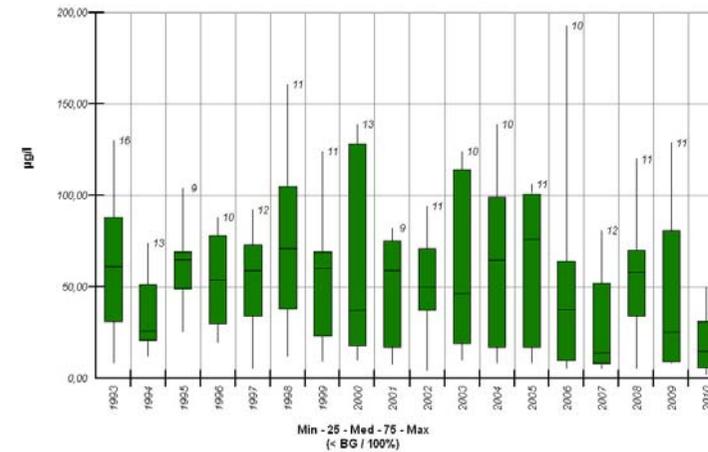

Some water quality parameters

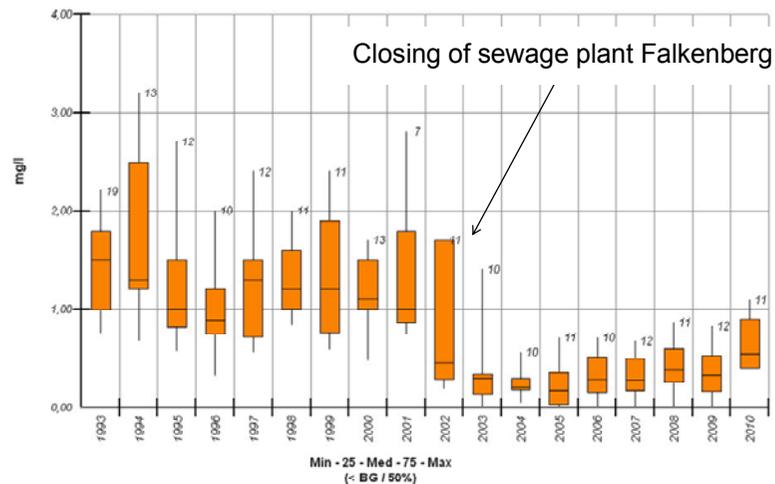

Oxygen saturation Index

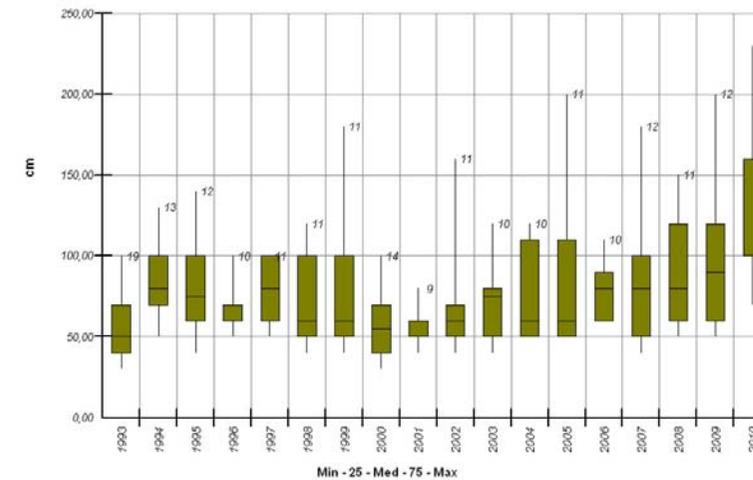

Chl a

Nitrate

Visibility depth

The lake has a problem

Sediments of the lake have been contaminated with heavy metals, mineral oil hydrocarbons and other organic contaminants due to the discharge of mainly industrial waste water in the course of about one century.

Furthermore, nutrients and easily biodegradable substances were carried into the lake

Algal blooms, oxygen deficiency, odour constraints, accelerated formation of digested sludge, substantial ecological instability

First Measures 1999 – 2001
(Sediment conditioning)

First Measures

- 1) Installation of a bulkhead with drive-through access

First Measures

- 1) Installation of a bulkhead with drive-through access
- 2) Detection and clearing munitions
phosphor bombs, grenades, weapons

Fotos: Leaflet "Hilfe für den Rummelsburger See"
Senate Department for Urban Development and the Environment, Berlin

First Measures

- 1) Installation of a bulkhead with drive-through access
- 2) Detection and clearing munitions
phosphor bombs, grenades, weapons
- 3) Partial sludge removal
expensive environmental disposal procedures

First Measures

- 1) Installation of a bulkhead with drive-through access
- 2) Detection and clearing munitions
phosphor bombs, grenades, weapons
- 3) Partial sludge removal
expensive environmental disposal procedures
- 4) Sediment conditioning with $\text{FeO}(\text{OH})$ and CaNO_3
- 5) Pneumatic destratification plant

Perforierte Rohre vor dem Verschweißen

Kompressoren

The questions

- What are the reasons for the biological deficiencies of the lake?
- What measures can be taken in order to improve the situation significantly?

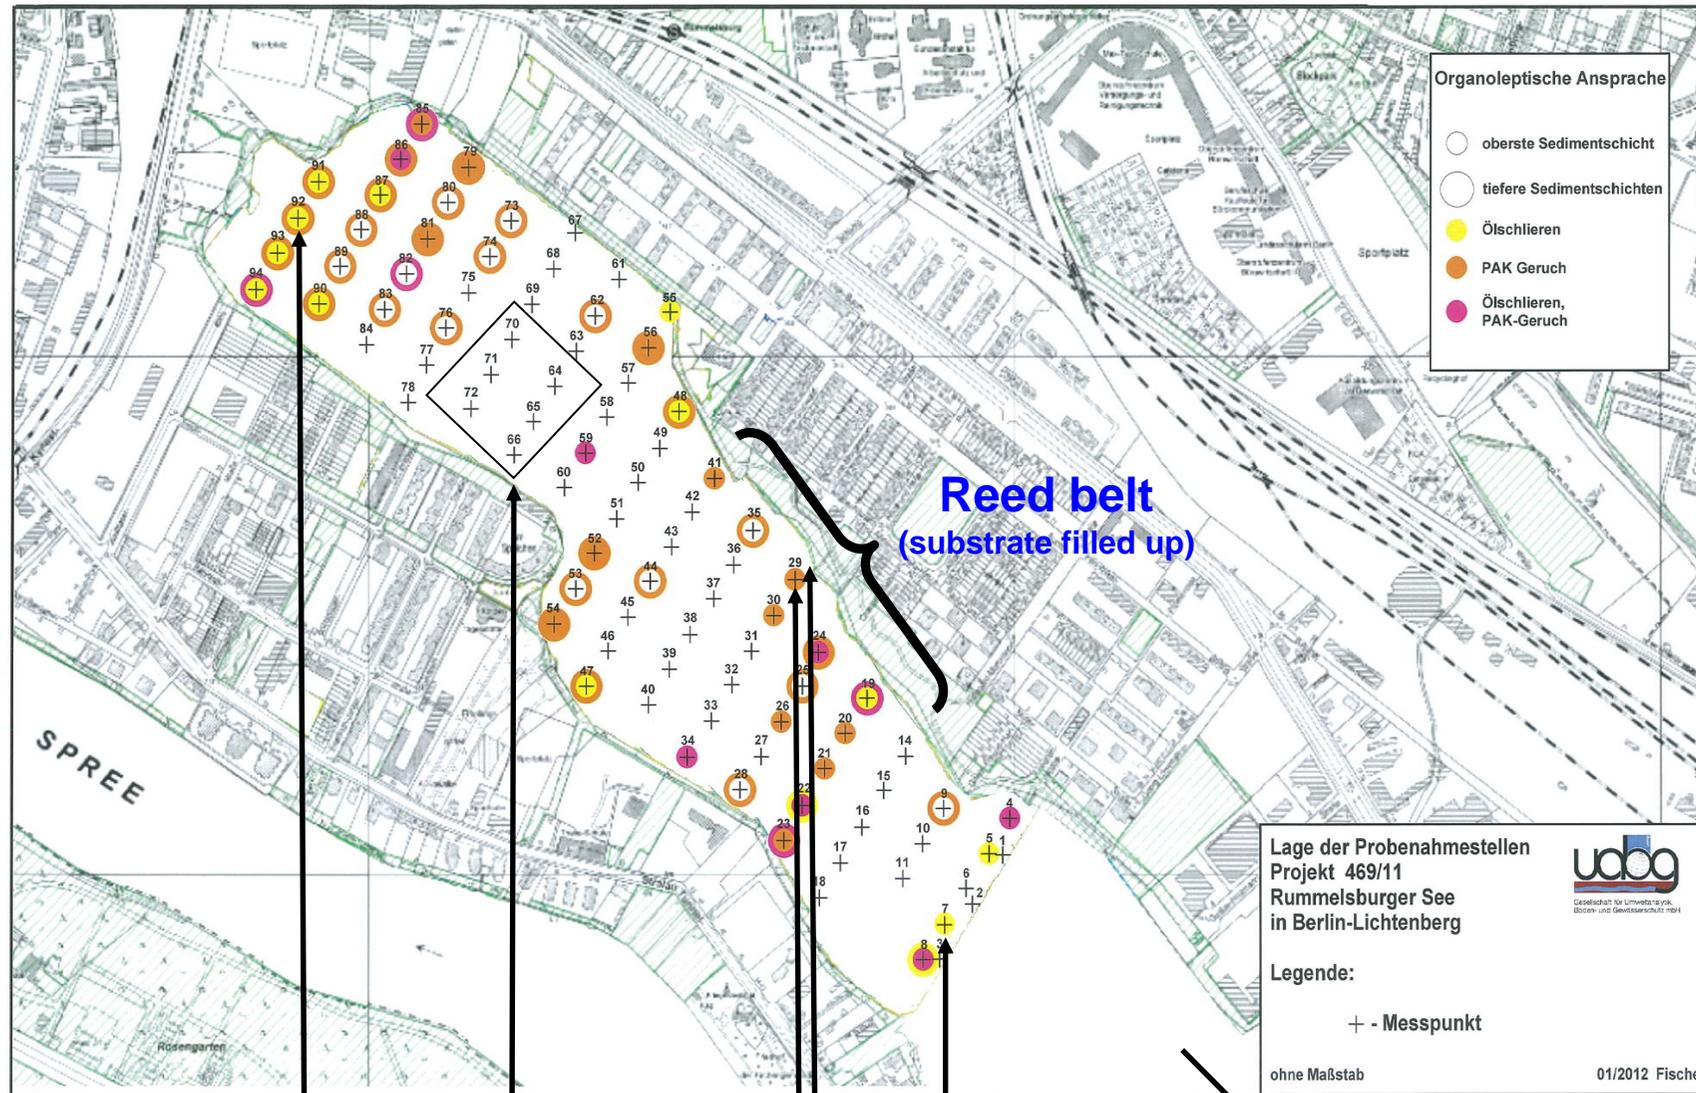

Attempt to answer the questions by a **sediment triad approach**:

- chemical analyses
- toxicological tests
- ecological analyses (macro zoobenthos)

plus

- sediment guideline approach

Sampling sites

120271

120265
sediment core
(only chem. anal.)

120263
120264

120262

120261
Spree „reference site“

Concentrations of organic contaminants
normalized to the <63 µm fraction of freshly deposited sediments:

400 – 1400	µg/kg (sum of 7 PCB),
90-700	µg/kg p,p'-DDD,
2500-6500	µg/kg mineral oil hydrocarbons,
55-370	mg/kg (sum of 16 EPA-PAHs),
1100-2400	µg/kg tributyltin and
9,7-76	ng I-TE/kg dioxin like activity.

GC/MS screening showed also:

- Long-chained hydrocarbons
- Alkylbenzenes
- Dichloro naphthalenes, Phenyl naphthalenes
- Mono- to tetra-alkylated PAHs
- Heterocyclic compounds (Furans, Thiophenes Quinolines)
- Phenoles
- Plasticisers
- Flame retardants
- Steroids

Metals, measured in the fine grained fraction < 63µm:

80-440 mg/kg Cr

9-46 mg/kg Cd

2,2-4,1 mg/kg Hg

1000-6400 mg/kg Cu

64-98 mg/kg Ni

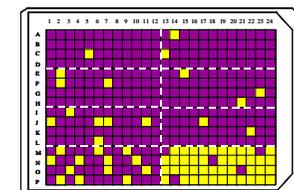

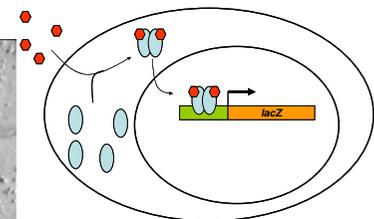

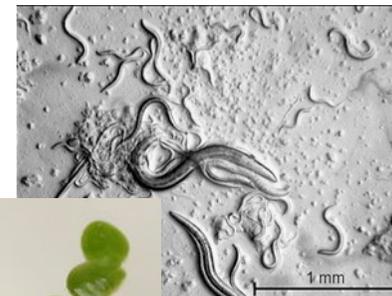

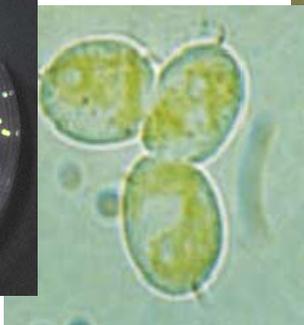

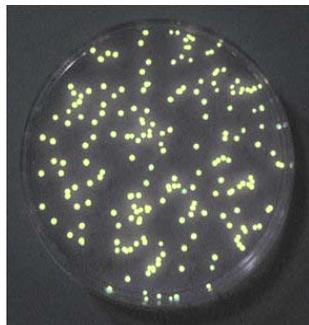

1600-2700 mg/kg Zn

340-830 mg/kg Pb

20-51 mg/kg As

Biotest battery

Biotest	Organism	Toxicity endpoint	Acute / chronic exposure	Samples	Standard
Luminescent bacteria test	<i>Aliivibrio fischeri</i>	Inhibition of Bioluminescence	Acute (30 min)	Pore water Elutriate	DIN EN ISO 11348-2
Green algae test	<i>Desmodesmus subspicatus</i>	Growth inhibition	Chronic (72 hrs)	Pore water Elutriate	DIN 38412-33
Daphnia test	<i>Daphnia magna</i>	Immobilisation	Acute (24 hrs)	Pore water Elutriate	DIN 38412-30
Lemna test	<i>Lemna minor</i>	Growth inhibition	Acute (7 d)	Pore water Elutriate	DIN EN ISO 20079
Myriophyllum test	<i>Myriophyllum aquaticum</i>	Growth inhibition	Acute (10 d)	Sediment	ISO 16191
Nematode test	<i>Caenorhabditis elegans</i>	Growth inhibition, fertility, reproduction	Chronic (96 hrs)	Pore water Elutriate Sediment	DIN ISO 10872
YES	<i>Saccharomyces cerevisiae</i>	ER activation	28 hrs	Pore water, elutriates, extracts	ISO NWIP in preparation
Ames test	<i>Salmonella typhimurium</i>	Mutagenicity	48 hrs	Pore water, elutriates, extracts	ISO 11350

Ecotoxicological sediment classification (BfG-Guidelines)

highest dilution without effect	dilution factor as exponential fraction	pT-value	toxicity classes		management categories	
			index	designation	toxicity class	designation
original sample	2^0	0	0	non-detectable toxicity	0	not contaminated
1:2	2^{-1}	1	I	very slightly toxic	I	non-hazardously contaminated
1:4	2^{-2}	2	II	slightly toxic	II	
1:8	2^{-3}	3	III	moderately toxic	III	critically contaminated
1:16	2^{-4}	4	IV	distinctly toxic	IV	
1:32	2^{-5}	5	V	highly toxic	V	hazardously contaminated
$\leq (1:64)$	$\leq 2^{-6}$	≥ 6	VI	extremely toxic	VI	

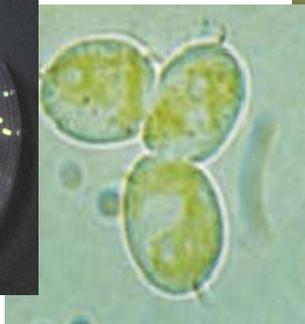

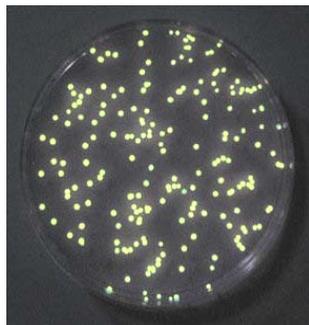

Classification of the ecotoxicological potential for dredged material and sediments with the pT-value system (Krebs 1988 & 2005)

Category (cat)	Description	Plants	Nematode Growth	Nematode Reproduction
1	no significant effect	< 20	< 25	< 50
2	medium effect	20-40	25-50	50-80
3	strong effect	> 40	> 50	> 80

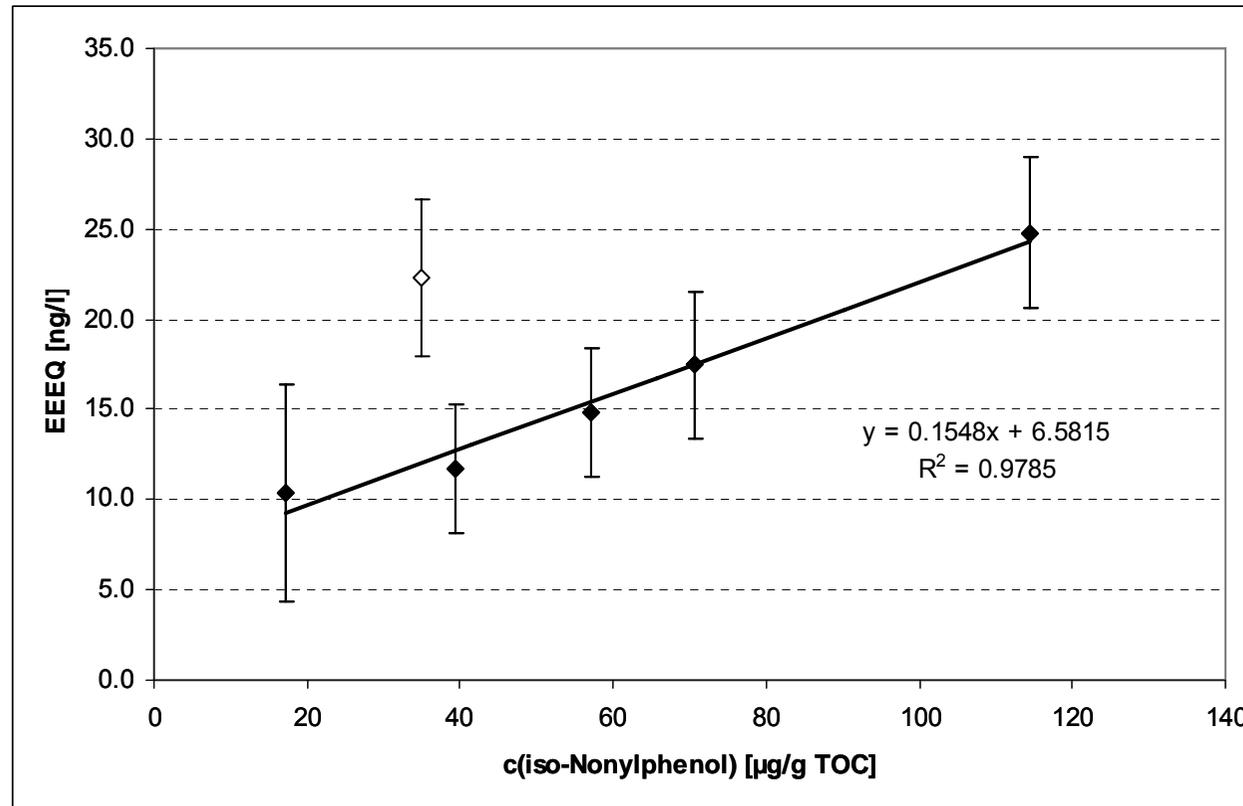

Estrogenicity *in vitro* (YES)

Estrogenic potentials of filtrated and non-filtrated pore water samples

Correlation estrogenic effects in pore water with iso-Nonylphenol

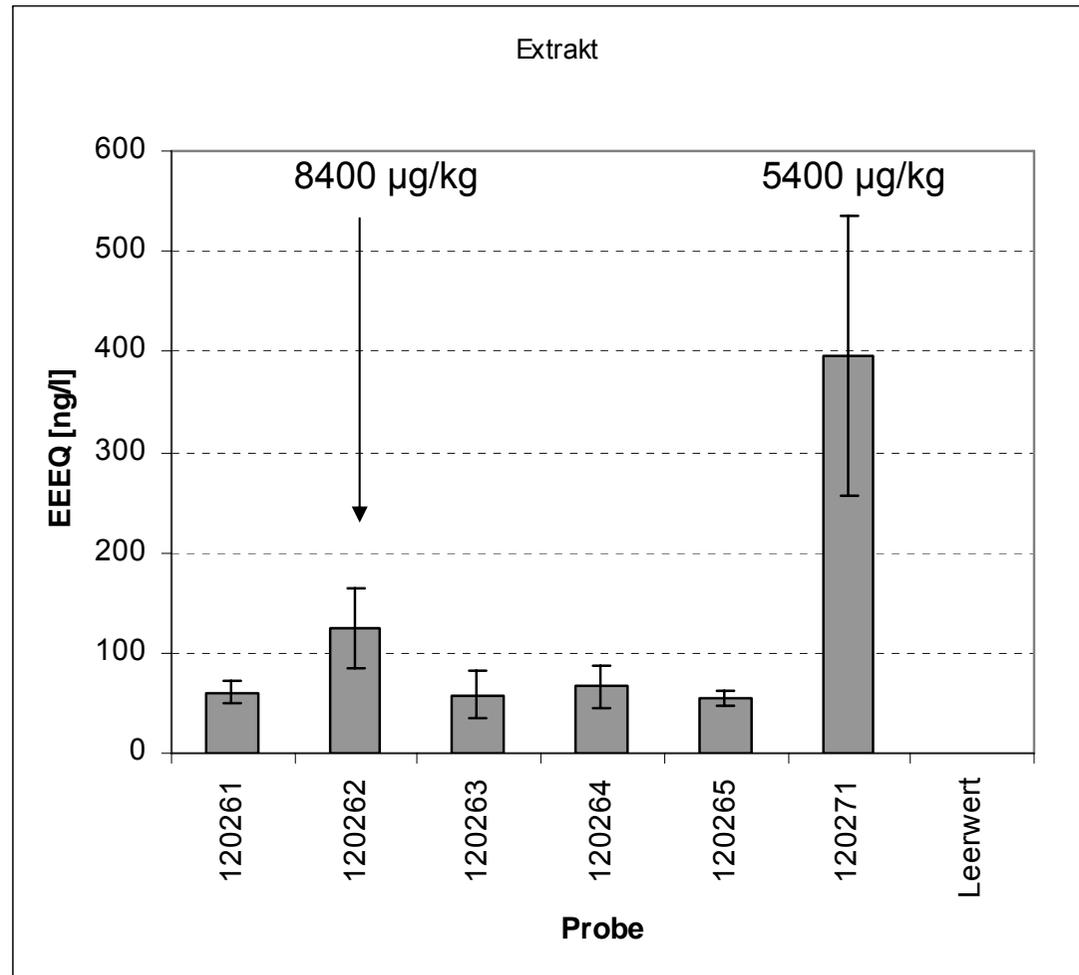

- c(iso-Nonylphenol) normalised to total organic carbon (TOC), to take availability for the water phase into account
- high correlation of chemical data and effect data
- sample 271 does not correlate → indication of other endocrine active compound(s)

Estrogenic effects extract

c(iso-Nonylphenol)

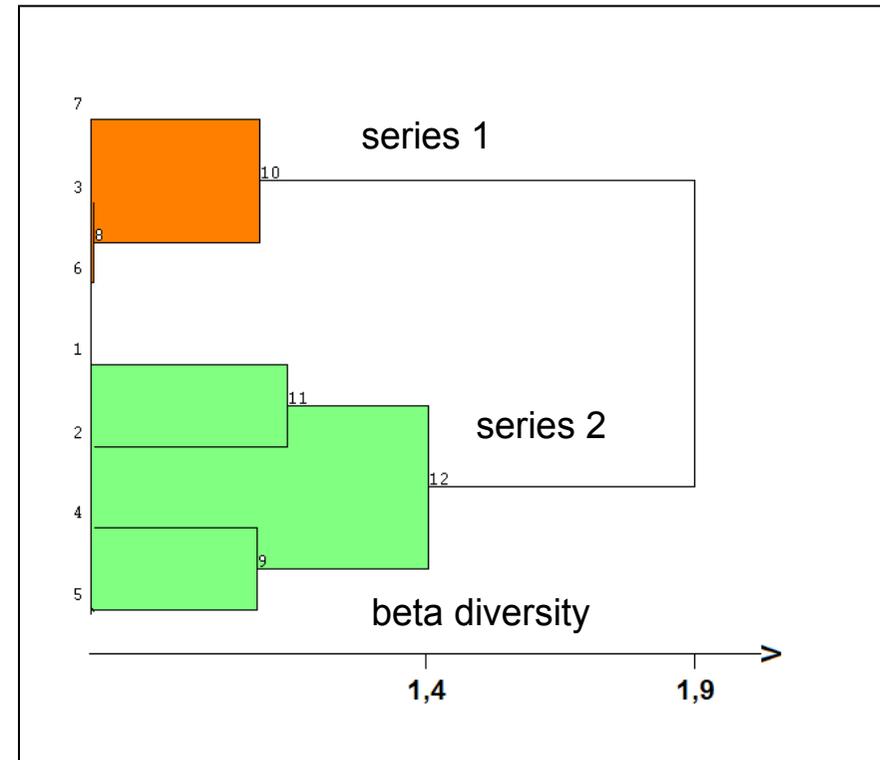

- Estrogenicity mainly
particle bound

- the two most contaminated samples (iso-Nonylphenol) show the highest effects
 - but: no correlation between concentrations of iso-Nonylphenol and effect
 - effect $P_{271} > \text{effect } P_{262}$ even though $c(\text{iNP})_{P_{271}} < c(\text{iNP})_{P_{262}}$
- in line with the observation with pore water (other estrogen active compound(s) in sample 271)

Characteristical taxa depend on sediment structural parameters

Sediment Quality Guidelines (SQGs)

derivation of numerical SQGs by empirical and theoretical approaches for the assessment of sediments

- Screening Level Concentration Approach (SLCA)
- Effects Range Approach (ERA)
- Effects Level Approach (ELA)
- Apparent Effects Threshold Approach (AETA)
- Equilibrium Partitioning Approach (EqPA)
- Logistic Regression Modelling Approach (LRMA)
- Consensus Approach (CA)

Sediment Quality Guidelines SQGs

Meaning of

TEC: Threshold Effect Concentrations ...if [] <: low toxicological risk

PEC: Probable Effect Concentrations ...if [] >: high toxicological risk

- TECs are concentrations below which adverse effects on benthic invertebrates are unlikely to be observed
- PECs are concentrations above which harmful effects on benthic invertebrates are likely to be observed
- PEC-quotients may be used to assess sediments with a complex mixture of contaminants

MacDonald, 2000: “TECs, PECs and PEC-quotients offer a reliable basis to classify non-toxic and toxic sediments”

Toxic potential (mean PEC-Q) of the lake sediments

Probability of toxicity

for benthic organisms in Lake Rummelsburg

Curve adopted from MacDonald et al. (2000)

Summary

- Lake Rummelsburg is area-wide contaminated, mainly due to past industrial production.
- From the river Spree further pollutants enter the lake.
- The „reference“ Spree is also contaminated, mainly by Cu and Pb, PCB and PAH (a new reference should be found and tested).
- Green algae, daphnia, and luminescent bacteria tests show no to low toxicity.
- *Lemna* test shows low to high toxicity.
- *C. elegans* shows moderate to very high toxicity.
- Estrogenicity: 10 to 25 ng /L EEQ [correlates with c(iso-Nonylphenol) normalised to TOC] and is mainly particle bound.
- Mutagenicity: not detectable in pore water. Detectable in extracts. Increasing with the metabolic competence of the test strains (data not shown).
- Characteristical MZB taxa depend on sediment structural parameters.
- SPEAR organisms are rare and depend on the sediment structure.
- Mean PEC-Q values predict high toxicity at all sites.

Main conclusions

The combination of

high chemical contamination with persistent organic and inorganic chemicals,

toxicity and

specific substrate composition

makes a natural repopulation scenario for the improvement of the biological diversity extremely improbable.

The study suggests that a significant improvement of the habitat could only be achieved by either a very cost-intensive removing of the sludges or by covering the sediments with uncontaminated substrate of appropriate structure or a combination of both.

→ the study will be completed by the assessment of a „true“ reference site with comparable sediment structure and low chemical contamination
