

## **CLH report**

### **Proposal for Harmonised Classification and Labelling**

**Based on Regulation (EC) No 1272/2008 (CLP Regulation),  
Annex VI, Part 2**

#### **Substance Name: Pyroxsulam**

**EC Number:** Not assigned

**CAS Number:** 422556-08-9

**Index Number:** Not assigned

**Contact details for dossier submitter:** UK Competent Authority

**Chemicals Regulation Directorate**

**Health and Safety Executive**

**United Kingdom**

**Version number:** 2

**Date:** May 2015

|----------|--|-----------|
| <b>1</b> | <b>PROPOSAL FOR HARMONISED CLASSIFICATION AND LABELLING .....</b>                              | <b>5</b>  |
| 1.1      | SUBSTANCE .....  | 5         |
| 1.2      | HARMONISED CLASSIFICATION AND LABELLING PROPOSAL .....   | 5         |
| 1.3      | PROPOSED HARMONISED CLASSIFICATION AND LABELLING BASED ON CLP REGULATION .....                 | 7         |
| <b>2</b> | <b>BACKGROUND TO THE CLH PROPOSAL .....</b>  | <b>10</b> |
| 2.1      | HISTORY OF THE PREVIOUS CLASSIFICATION AND LABELLING .....                                     | 10        |
| 2.2      | SHORT SUMMARY OF THE SCIENTIFIC JUSTIFICATION FOR THE CLH PROPOSAL .....                       | 10        |
| 2.3      | CURRENT HARMONISED CLASSIFICATION AND LABELLING .....  | 11        |
| 2.3.1    | <i>Current classification and labelling in Annex VI, Table 3.1 in the CLP Regulation .....</i> | <i>11</i> |
| 2.4      | CURRENT SELF-CLASSIFICATION AND LABELLING .....  | 11        |
| 2.4.1    | <i>Current self-classification and labelling .....</i>   | <i>11</i> |
| <b>3</b> | <b>JUSTIFICATION THAT ACTION IS NEEDED AT COMMUNITY LEVEL .....</b>                            | <b>11</b> |

## Part B.

### SCIENTIFIC EVALUATION OF THE DATA

|          |   |           |
|----------|---|-----------|
| <b>1</b> | <b>IDENTITY OF THE SUBSTANCE .....</b>  | <b>12</b> |
| 1.1      | NAME AND OTHER IDENTIFIERS OF THE SUBSTANCE .....                                       | 12        |
| 1.2      | COMPOSITION OF THE SUBSTANCE .....  | 13        |
| 1.2.1    | <i>Composition of test material .....</i>   | <i>13</i> |
| 1.3      | PHYSICO-CHEMICAL PROPERTIES .....   | 14        |
| <b>2</b> | <b>MANUFACTURE AND USES .....</b>   | <b>15</b> |
| 2.1      | MANUFACTURE .....   | 15        |
| 2.2      | IDENTIFIED USES .....   | 15        |
| <b>3</b> | <b>CLASSIFICATION FOR PHYSICO-CHEMICAL PROPERTIES .....</b>                             | <b>16</b> |
| 3.1      | PHYSICO-CHEMICAL HAZARDS .....  | 16        |
| 3.1.1    | <i>Summary and discussion of Physico-Chemical Hazards .....</i>                         | <i>16</i> |
| 3.1.2    | <i>Comparison with criteria .....</i>   | <i>16</i> |
| 3.1.3    | <i>Conclusions on classification and labelling .....</i>                                | <i>16</i> |
| <b>4</b> | <b>HUMAN HEALTH HAZARD ASSESSMENT .....</b>   | <b>17</b> |
| 4.1      | TOXICOKINETICS (ABSORPTION, METABOLISM, DISTRIBUTION AND ELIMINATION) .....             | 17        |
| 4.1.1    | <i>Non-human information .....</i>  | <i>17</i> |
| 4.1.2    | <i>Human information .....</i>  | <i>17</i> |
| 4.1.3    | <i>Summary and discussion on toxicokinetics .....</i>                                   | <i>18</i> |
| 4.2      | ACUTE TOXICITY .....  | 18        |
| 4.2.1    | <i>Non-human information .....</i>  | <i>19</i> |
| 4.2.2    | <i>Human information .....</i>  | <i>19</i> |
| 4.2.3    | <i>Summary and discussion of acute toxicity .....</i>                                   | <i>19</i> |
| 4.2.4    | <i>Comparison with criteria .....</i>   | <i>19</i> |
| 4.2.5    | <i>Conclusions on classification and labelling .....</i>                                | <i>19</i> |
| 4.3      | SPECIFIC TARGET ORGAN TOXICITY – SINGLE EXPOSURE (STOT SE) .....                        | 19        |

| 3.10. | Aspiration hazard                                  | Not classified   | Not applicable | Not classified | conclusive but not sufficient for classification |

|      |                                      |  |   |                |  |
|------|--------------------------------------|--|---|----------------|--|
| 4.1. | Hazardous to the aquatic environment | Aquatic Acute 1; H400 - Very toxic to aquatic life<br>Aquatic Chronic 1; H410 - Very toxic to aquatic life with long lasting effects | Acute M factor = 100<br>Chronic M factor = 100) |                |  |
| 5.1. | Hazardous to the ozone layer         | Not classified   | Not applicable                                  | Not classified | conclusive but not sufficient for classification |

<sup>1)</sup> Including specific concentration limits (SCLs) and M-factors

<sup>2)</sup> Data lacking, inconclusive, or conclusive but not sufficient for classification

**Labelling:**

Pictogram(s): GHS07, GHS09

Signal word: Warning

Hazard statements: H317: May cause an allergic skin reaction  
H410 - Very toxic to aquatic life with long lasting effects

Precautionary statements: Not required, P statements are not included in Annex VI

**Proposed notes assigned to an entry:** None

## 2 BACKGROUND TO THE CLH PROPOSAL

### 2.1 History of the previous classification and labelling

Pyroxsulam is a pesticide active substance approved under Directive 91/414/EEC (subsequently replaced by EU Regulation 1107/2009), for which the UK were the Rapporteur Member State (RMS). Refer to Commission Implementing Regulation (EU) No 1176/2013 of 20 November 2013. There is no entry on Annex VI of CLP and there have been no previous classification and labelling discussions for this substance. Therefore, in accordance with Article 36(2) of the CLP Regulation, pyroxsulam should now be considered for harmonised classification and labelling. As the substance does not have a current entry on Annex VI of CLP this proposal considers all physical, human health and environmental hazard classes.

At the time of submission the substance is not registered under REACH.

### 2.2 Short summary of the scientific justification for the CLH proposal

Pyroxsulam is a member of the triazolopyrimidine sulfonamides, a class of herbicides known to inhibit the plant enzyme acetolactate synthase (ALS). It is broadly active on annual grass and broadleaf weeds, with some activity on certain perennial weed species.

The conclusion of the EFSA peer review process (EFSA Journal 2013;11(4):3182) noted concern for skin sensitisation and carcinogenicity. However, there was no consensus between the experts regarding the latter. Classification with Aquatic Acute 1; H400 and Aquatic Acute 1; H410 were also considered appropriate.

In a standard guinea pig maximisation study, the sensitisation response was 80 % in treated animals receiving an intradermal induction of 5% pyroxsulam. Classification in Skin Sens 1: H317 – May cause an allergic skin reaction is therefore proposed. Refer to section 4.6 of this report for full details.

Large granular lymphocyte leukaemia (LGL) in Fischer 344 rats and hepatocellular adenomas and carcinomas in mice were observed. The leukaemia was not considered to be related to treatment and therefore was not considered for classification. The increased incidence of liver adenomas and carcinomas in the mouse was slightly higher than the contemporaneous and laboratory historical control in males, but the carcinomas were within the control range provided for Charles River Labs (from which the mice were sourced). In addition, these findings occurred in male mice only, which appeared to be susceptible to liver tumour formation with multiple adenomas (rather than single incidences) observed in the livers of both control and treated animals. In conclusion, it is considered that there is insufficient evidence in this study to conclude that there is a treatment-related carcinogenic effect of pyroxsulam. Refer to 4.10 of this report for full details.

Aquatic acute toxicity data on pyroxsulam are available for fish, invertebrates, algae and aquatic plants. Aquatic plants are the most acutely sensitive trophic group. The lowest L(E)C<sub>50</sub> value is a 7-day E<sub>r</sub>C<sub>50</sub> of 0.00388 mg/l for *Lemna minor* in the range 0.001 to ≤0.01 mg/l. On this basis pyroxsulam should be classified as Aquatic Acute 1 with an M factor of 100.

Adequate chronic toxicity data on pyroxsulam are available for fish, invertebrates, algae and aquatic plants. The lowest value is a 7-day NOE<sub>r</sub>C for *Lemna minor* of 0.0007 mg/l. Given this is in the

range 0.0001 to  $\leq 0.001$  mg/l and the substance is considered non-rapidly degradable, pyroxsulam should be classified as Aquatic Chronic 1 with an M factor of 100.

## 2.3 Current harmonised classification and labelling

### 2.3.1 Current classification and labelling in Annex VI, Table 3.1 in the CLP Regulation

Not currently listed.

## 2.4 Current self-classification and labelling

### 2.4.1 Current self-classification and labelling

The following entries are included in the classification and labelling inventory at the time of submission

| Classification                                       |                          | Labelling                |  |                                 |

## 3 JUSTIFICATION THAT ACTION IS NEEDED AT COMMUNITY LEVEL

Pyroxsulam is a pesticide active substance approved under Directive 91/414/EEC (subsequently replaced by EU Regulation 1107/2009), for which the UK were the Rapporteur Member State (RMS). Refer to Commission Implementing Regulation (EU) No 1176/2013 of 20 November 2013. There is no entry on Annex VI of CLP and therefore, in accordance with Article 36(2) of the CLP Regulation, pyroxsulam should now be considered for harmonised classification and labelling. All physical, human health and environmental hazard classes are considered in this report.

Reference should be made to the Draft Assessment Report (DAR) – Pyroxsulam - Volume 3, Annex B2: Physical and Chemical Properties – January 2012

## 2 MANUFACTURE AND USES

### 2.1 Manufacture

Pyroxsulam is manufactured outside of the EU.

### 2.2 Identified uses

Pyroxsulam is placed on the market within the EU as an herbicide.

### 3 CLASSIFICATION FOR PHYSICO-CHEMICAL PROPERTIES

**Table 9: Summary table for relevant physico-chemical studies**

| Method           | Results | Remarks | Reference |
|------------------|---------|---------|-----------|
| Refer to table 8 |         |         |           |

#### 3.1 Physico-chemical Hazards

##### 3.1.1 Summary and discussion of Physico-Chemical Hazards

##### 3.1.2 Comparison with criteria

In a standard flammability study (EEC Method A10), pyroxsulam ignited but failed to sustain combustion. As such, it does not meet the criteria for classification as a flammable solid. The self ignition temperature was found to be > 400 °C. Further, experience in handling and use indicates that it is not a pyrophoric solid and does not emit flammable gas on contact with water.

In a standard study (EEC Method A14), pyroxsulam did not exhibit any explosive properties. As such, it does not meet the criteria for classification as an explosive substance.

Finally, in a standard study (EEC Method A17), pyroxsulam ignited and charred, but did not burn to completion. As such, it is not classified as an oxidising solid.

## 4 HUMAN HEALTH HAZARD ASSESSMENT

References are taken from the Draft Assessment Report (DAR) – Pyroxsulam - Volume 3, Annex B6: Toxicology and Metabolism – January 2012

### 4.1 Toxicokinetics (absorption, metabolism, distribution and elimination)

#### 4.1.1 Non-human information

The following summary is derived from the Pesticide Assessment Report made for the review under Directive 91/414/EEC.

The toxicokinetics of pyroxsulam have been investigated in two species: rat and mouse.

In the rat study, pyroxsulam was shown to be rapidly absorbed with around 74-78 % of the dose being absorbed after administration with 10 mg/kg bw/day. The 1000 mg/kg bw/day was absorbed to a lesser extent. Of the tissues investigated, highest systemic levels occurred in the plasma, liver and kidney. Pyroxsulam was rapidly excreted in the urine and faeces (nearly 100 % of the absorbed dose within 48 h). Pyroxsulam was mostly excreted unchanged (85-90% of administered dose). The only identified metabolite was 2-desmethyl-XDE-742, which was present in both urine and faeces (at least 5 % of low dose administered). There were no differences in findings between the two labelling positions (labelled in the triazole or pyridine rings), nor between single or repeat dosing. Notably, there was no evidence for metabolic induction (no alteration in metabolism of pyroxsulam) as a result of repeat dosing with unlabelled pyroxsulam. The rapid and extensive excretion with very low levels in carcass at 38 h post dose (< 1% of administered dose) suggests there is little potential for accumulation.

In the mouse study, pyroxsulam was rapidly absorbed. After oral dosing with 10 mg/kg bw/day, about 60 % was absorbed; a lesser percentage was absorbed at 1000 mg/kg bw/day. Limited data indicate that liver concentrations of radiolabel rose to significantly higher levels in males than females. Radiolabel was cleared quickly from plasma, RBC and liver during the initial elimination phase ( $t_{1/2}$  of 2-3h) and subsequently more slowly (especially from the liver) at the high dose. The slow elimination from the liver, will favour accumulation of pyroxsulam/metabolites in the liver on repeated dietary exposure. Of the limited tissues investigated at 72 h, highest systemic levels were in the liver.

Compared to male rats, at the plasma  $C_{max}$  following an oral dose of 10 mg/kg bw, the concentration of radiolabel in the liver was slightly higher for male mice, but decreased to similar levels in both species at 2h and 48h. It is also notable that at 48h (only timepoint with data available) after dosing with 1000 mg/kg bw, the concentration in the liver of male rats (16.7 ug-eq./g) was slightly higher than in the male mice (8.2 ug-eq./g).

Pyroxsulam-derived radioactivity was rapidly and extensively excreted in urine and faeces (93-100 % within 24 h). Excretion was mainly in urine at 10 and 100 mg/kg bw, but mainly in faeces at 1000 mg/kg bw.

#### 4.1.2 Human information

No information available

### 4.1.3 Summary and discussion on toxicokinetics

The toxicokinetics of pyroxsulam was investigated orally in rats (single and repeated administration) and mice (single dose only). Following single (rats and mice) and repeat administration (rat only), pyroxsulam was well absorbed. In rats, distribution was highest in the plasma, liver and kidney. Only a small proportion of pyroxsulam was metabolised. Excretion was via both the urine and faeces in rats and mainly via the urine in mice at the low dose and via the faeces at the high dose. There was no evidence of bioaccumulation.

## 4.2 Acute toxicity

**Table 10: Summary table of relevant acute toxicity studies**

| Acute Oral   |                  |   |
|--|------------------|---|
| Method   | LD <sub>50</sub> | Observations and remarks  |
| OECD 423 (2001)<br>GLP<br>6 female Wistar rats<br>Single dose of 2000 mg/kg bw<br><i>Gamer and Leibold (2003a)</i>   | > 2000 mg/kg bw  | An initial dose (2000 mg/kg bw/day) was given to 3 fasted rats. As none died a further 3 rats were dosed in the same manner.<br><br>No mortality or effects observed  |
| Acute Inhalation   |                  |   |
| Method   | LC <sub>50</sub> | Observations and remarks  |
| OECD 403 (1981)<br>GLP<br>5 F344 rats/sex<br>Exposed nose only for 4 h to 5.12 mg/L (dust/aerosol)<br>MMAD – 3.6 microns<br><i>Lowe (2007a)</i>                      | > 5.12 mg/L      | There were no deaths or clinical signs of toxicity. Although most rats had lost weight by day 1 or 3 (post-exposure), all animals surpassed their pre-exposure weight by day 7 and continued to gain body weight through day 14. There were no treatment-related lesions at necropsy. |
| Acute Dermal   |                  |   |
| Method   | LD <sub>50</sub> | Observations and remarks  |
| OECD 402 (1987)<br>GLP<br>5 Wistar rats/sex<br>Single dose of 2000 mg/kg bw<br>Vehicle: doubly distilled water<br>Semi occlusive<br><i>Gamer and Leibold (2003b)</i> | > 2000 mg/kg bw  | No mortality or adverse effects observed  |

#### **4.2.1 Non-human information**

##### **4.2.1.1 Acute toxicity: oral**

An oral LD<sub>50</sub> of > 2000 mg/kg bw/day was derived from a study conducted in rats.

##### **4.2.1.2 Acute toxicity: inhalation**

An inhalation 4 hr LC<sub>50</sub> of > 5.12 mg/L was derived from a study conducted in rats.

##### **4.2.1.3 Acute toxicity: dermal**

A dermal LD<sub>50</sub> of > 2000 mg/kg bw/day was derived from a study conducted in rats.

##### **4.2.1.4 Acute toxicity: other routes**

No information available

#### **4.2.2 Human information**

No information available

#### **4.2.3 Summary and discussion of acute toxicity**

See section 4.2.1

#### **4.2.4 Comparison with criteria**

Via the oral, inhalation and dermal routes, the LD<sub>50</sub> values were higher than the respective guidance values (2000 mg/kg, 5 mg/l and 2000 mg/kg respectively); no classification is required.

#### **4.2.5 Conclusions on classification and labelling**

|   |
|---|
| <b>Not Classified: conclusive but not sufficient for classification</b> |
|---|

### **4.3 Specific target organ toxicity – single exposure (STOT SE)**

#### **4.3.1 Summary and discussion of Specific target organ toxicity – single exposure**

No clinical signs or changes in organs were observed in any of the acute studies (table 10).

#### **4.3.2 Comparison with criteria**

Substances that have produced significant toxicity in humans or that, on the basis of evidence from studies in experimental animals, can be presumed to have the potential to produce significant toxicity in humans following single exposure are classified in STOT-SE 1 or 2. Classification is supported by evidence associating single exposure to the substance with a consistent and identifiable toxic effect.

Classification in STOT-SE 3 is reserved for transient target organ effects and is limited to substances that have narcotic effects or cause respiratory tract irritation.

Since no clinical signs or changes in organs were observed (table 10), the criteria for STOT SE are not met

### 4.3.3 Conclusions on classification and labelling

|   |
|---|
| <b>Not Classified: conclusive but not sufficient for classification</b> |
|---|

## 4.4 Irritation

### 4.4.1 Skin irritation

**Table 11: Summary table of relevant skin irritation studies**

| Method  | Results   | Remarks   | Reference   |
|---|---|---|---|
| OECD 404 (2002)<br>GLP<br>0.5g of test substance moistened with distilled water and applied for 4 hours.<br><br>3 New Zealand rabbits<br><br>Semi-Occlusive | Slight erythema (grade 1) was observed in all animals immediately and up to 1 hour after removal of the patch.<br><br>No other cutaneous reactions were observed during the study.<br><br>Mean scores over 24, 48 and 72 hours were 0 for erythema and oedema | Pyroxsulam showed slight transient irritation at the 1 hour time point only | Kaufmann and Leibold (2003a) and Kaufmann (2006a) |

#### 4.4.1.1 Non-human information

The skin irritation potential of pyroxsulam has been investigated in one standard guideline study in rabbits. Only slight transient irritation was observed.

#### 4.4.1.2 Human information

No information available

#### 4.4.1.3 Summary and discussion of skin irritation

The skin irritation potential of pyroxsulam has been investigated in one standard guideline study in rabbits. Slight transient irritation was observed at the 1 hr observation only.

#### 4.4.1.4 Comparison with criteria

No oedema or erythema was observed over the time points relevant for classification (24, 48 and 72 hours); therefore, no classification for skin irritation is required.

**4.4.1.5 Conclusions on classification and labelling****Not Classified: conclusive but not sufficient for classification****4.4.2 Eye irritation****Table 12: Summary table of relevant eye irritation studies**

| Method  | Results   | Remarks  | Reference   |
|---|---|--|---|
| OECD 405 (2002)<br>GLP<br><br>0.1 ml of test substance was applied for 1 hour.<br><br>3 New Zealand rabbits (application was a stepwise procedure starting with one animal and then two additional animals) | Slight conjunctival redness (grade 1) was observed in all animals 1 hour after application. This persisted in two animals up to 24 hours and in one animal up to 48 hours<br><br>Grade 1 chemosis was observed in one animal between 1-24 hour<br><br>Mean scores for each animal calculated over 24, 48 and 72 hours<br><br>0, 0 and 0 for corneal opacity and iris lesions<br>0.7, 0.3, 0.3 for redness of the conjunctiva<br>0, 0 and 0.3 for chemosis | Injected scleral vessels in a circumscribed area were noted in one animal after 24 hours | Kaufmann and Leibold (2003b) and Kaufmann (2006b) |

**4.4.2.1 Non-human information**

The eye irritation potential of pyroxsulam has been investigated in a standard guideline study. No effects on the cornea or iris were noted. Effects on the conjunctivae were limited to mild erythema and oedema.

**4.4.2.2 Human information**

No information available

**4.4.2.3 Summary and discussion of eye irritation**

The eye irritation potential of pyroxsulam has been investigated in a standard guideline study. No effects on the cornea or iris were noted. Effects on the conjunctivae were limited to erythema and mild oedema.

**4.4.2.4 Comparison with criteria**

No effects in the iris or cornea were noted. The mean scores for each animal calculated over 24, 48 and 72 hours for erythema and oedema of the conjunctivae were less than the guidance value of 2. No classification is required.

**4.4.2.5 Conclusions on classification and labelling**

|   |
|---|
| <b>Not Classified: conclusive but not sufficient for classification</b> |
|---|

**4.4.3 Respiratory tract irritation****4.4.3.1 Non-human information**

This endpoint was not investigated directly; however, no signs of respiratory irritation were observed in the acute inhalation study (see section 4.2).

**4.4.3.2 Human information**

No information available

**4.4.3.3 Summary and discussion of respiratory tract irritation**

This endpoint was not investigated directly; however, no signs of respiratory irritation were observed in the acute inhalation study (see section 4.2).

**4.4.3.4 Comparison with criteria**

No signs of respiratory tract irritation were observed.

**4.4.3.5 Conclusions on classification and labelling**

|                                     |
|-------------------------------------|
| <b>Not Classified: Data lacking</b> |
|-------------------------------------|

**4.5 Corrosivity****Table 13: Summary table of relevant corrosivity studies**

| Method            | Results | Remarks | Reference |
|-------------------|---------|---------|-----------|
| Refer to table 11 |         |         |           |

**4.5.1 Non-human information**

Pyroxsulam is not irritating to skin (see section 4.4)

**4.5.2 Human information**

No information available

### 4.5.3 Summary and discussion of corrosivity

Pyroxsulam is not irritating to skin (see section 4.4)

### 4.5.4 Comparison with criteria

No signs of corrosivity were observed in an *in vivo* skin irritation study.

### 4.5.5 Conclusions on classification and labelling

|   |
|---|
| <b>Not Classified: conclusive but not sufficient for classification</b> |

## 4.6 Sensitisation

### 4.6.1 Skin sensitisation

**Table 14: Summary table of relevant skin sensitisation studies**

| Species/Method   | Doses   | No. sensitised/total no.  | Result   | Reference                |
|--|---|---|----------|--------------------------|
| OECD 406 (1992)<br>GLP<br>Guinea-pig/Dunkin-Hartley<br>10 control animals<br>20 test animals<br><br>Intradermal induction performed on day 0 and epicutaneous induction on day 7.<br>Challenge was 14 days after the epicutaneous induction. | <u>Induction:</u><br><u>Intradermal:</u> 5 % pyroxsulam in 1 % CMC (carboxymethylcellulose) sodium solution in water<br><u>Topical:</u> 50 % pyroxsulam in 1 % CMC-solution in water<br><u>Challenge:</u> 25 % pyroxsulam in 1 % CMC-solution water<br><br>Erythema and/or swelling observed following intradermal and topical induction. | <u>Test:</u><br>24 h: 16/20<br>48 h: 15/20<br><br><u>Negative Control:</u><br>0/10 at 24 and 48 h<br><br>Positive control:<br>alpha-hexylcinnamaldehyde, techn. 85% showed test system was able to detect sensitizing compounds | Positive | Gamer and Leibold (2004) |

#### 4.6.1.1 Non-human information

The skin sensitisation potential has been investigated in a standard maximisation study. Positive responses were observed in 16/20 animals at 24 hours and 15/20 animals at 48 hours compared to 0/10 in the control.

**4.6.1.2 Human information**

No information is available.

**4.6.1.3 Summary and discussion of skin sensitisation**

The skin sensitisation potential has been investigated in a standard maximisation study. Positive responses were observed in 16/20 animals (80%) at 24 hours and 15/20 (75%) animals at 48 hours compared to 0/10 in the control.

**4.6.1.4 Comparison with criteria**

A substance is classified in Category 1A where

- a) there is a  $\geq 30\%$  response in animals receiving an intradermal induction dose of  $\leq 0.1\%$  or
- b) there is  $\geq 60\%$  response in animals receiving an intradermal induction dose of  $> 0.1\%$  and  $\leq 1\%$  in a GPMT.

A substance is classified in Category 1B where

- a) there is a  $\geq 30\%$  to  $<60\%$  response in animals receiving an intradermal induction dose of  $> 0.1\%$  and  $\leq 1\%$  or
- b) there is a  $\geq 30\%$  response in animals receiving an intradermal induction dose of  $> 1\%$  in a GPMT;

where there is no information to suggest that classification in Category 1A should be considered,

The sensitisation response in the available Guinea-Pig maximisation study with pyroxsulam was 80%, with an intradermal induction of 5%. Whilst this meets the criteria for classification in Category 1B, it should be noted that a relatively high response (80%) was observed with an induction dose of 5% and no data are available from standard studies at lower induction concentrations. As such it could be that classification in Category 1A can not be excluded and a simple argument for classification in Category 1 can be made.

**4.6.1.5 Conclusions on classification and labelling**

**Skin Sens 1; H317 May cause an allergic skin reaction**

**4.6.2 Respiratory sensitisation**

**Table 15: Summary table of relevant respiratory sensitisation studies**

## 4.7.1 Non-human information

### 4.7.1.1 Repeated dose toxicity: oral

#### *Sub-acute toxicity*

Information on sub-acute toxicity is available from a 28-day study in rats and a 28-day and a 90-day study in dogs.

There were no adverse effects observed below the relevant guidance values for classification (300 mg/kg bw/day) in any study. At dose levels above the cut-off (~1000 mg/kg bw/day) effects included reduction in bodyweight and slight changes in clinical chemistry parameters (ALT and ↑ serum cholesterol)<sup>1</sup>. In both dog studies, liver weights were also increased, and were accompanied by associated histopathological changes in the 90-day study.

#### *Sub-chronic toxicity*

Information on sub-chronic toxicity comes from a 90-day study in rats, a 90-day study in mice and a one-year study in dogs.

There were no adverse effects observed below the relevant guidance values for classification (100 mg/kg bw/day). At dose levels above the guidance values (> 589 mg/kg bw/day) effects including

<sup>1</sup> In a number of rat studies, perineal urine staining was observed. This effect was not considered adverse and is not discussed further.

reductions in bodyweight (rats and dogs only), slight, non-adverse, changes in clinical chemistry (↑ alkaline phosphatase and ↑ serum cholesterol) and increased liver weights were observed in all species unless specified.

#### *Chronic toxicity*

Information on chronic toxicity comes from a study in rats and a study in mice (see section 4.10).

In both studies, effects were only noted at the limit dose (1000 mg/kg bw/day) and were comparable to those observed in the other studies (bodyweight, liver effects, and clinical chemistry changes). The only exception to this was an increase in kidney weight (relative and absolute) observed in mice.

#### **4.7.1.2 Repeated dose toxicity: inhalation**

No information available.

#### **4.7.1.3 Repeated dose toxicity: dermal**

Limited information on sub-acute toxicity is available from a 14-day study in rats. In this study no effects were observed at the limit dose. No classification is warranted.

#### **4.7.1.4 Repeated dose toxicity: other routes**

No information available.

#### **4.7.1.5 Human information**

No information available.

#### **4.7.1.6 Other relevant information**

Not applicable

#### **4.7.1.7 Summary and discussion of repeated dose toxicity**

See sections 4.7.1.1 and 4.7.1.3

### **4.8 Specific target organ toxicity (CLP Regulation) – repeated exposure (STOT RE)**

#### **4.8.1 Summary and discussion of repeated dose toxicity findings relevant for classification as STOT RE according to CLP Regulation**

Information on pyroxsulam is available from oral studies in rats, mice and dogs. There is also information available from a dermal study in rats.

The rat data show that there are no serious adverse effects of pyroxsulam below the guidance values (300 mg/kg bw/day in a 90-day study in rats) for classification, with effects occurring only at higher dose levels (reduced bodyweight and liver effects). The mouse and dog data confirm pyroxsulam is of low toxicity. The main adverse effects were reduced bodyweight (dog) and effects on the liver (both dogs and mice).

The results of a 14-day dermal range-finding study showed no effects up to the limit dose.

**4.8.2 Comparison with criteria of repeated dose toxicity findings relevant for classification as STOT RE**

The available information indicates that classification for repeated dose toxicity is not warranted as no significant adverse effects were observed below the guidance values for classification.

**4.8.3 Conclusions on classification and labelling of repeated dose toxicity findings relevant for classification as STOT RE**

**Not Classified: conclusive but not sufficient for classification**

## 4.9 Germ cell mutagenicity (Mutagenicity)

Table 17: Summary table of relevant in vitro and in vivo mutagenicity studies

#### 4.9.1 Non-human information

##### 4.9.1.1 In vitro data

The genotoxicity of pyroxsulam has been investigated in an Ames test, an *in vitro* cytogenetics study and an *in vitro* mammalian cell gene mutation study. Positive controls were included in all assays and showed the expected responses. The result of all assays was negative.

##### 4.9.1.2 In vivo data

The genotoxicity of pyroxsulam has been investigated *in vivo* in a mouse micronucleus study and an unscheduled DNA synthesis (UDS) study in mouse livers. The results of both studies were negative. No deaths or cytotoxicity was observed in either study. This is not considered to be a problem as toxicokinetic studies have shown pyroxsulam to be well distributed. In addition, with regards the UDS study, the liver has been identified as the target organ for this substance.

#### 4.9.2 Human information

No information available

#### 4.9.3 Other relevant information

Not applicable

#### 4.9.4 Summary and discussion of mutagenicity

Data indicate pyroxsulam is not mutagenic *in vitro* or *in vivo*.

**4.9.5 Comparison with criteria**

Data indicate pyroxsulam is not mutagenic *in vitro* or *in vivo* and classification as a germ cell mutagen is not warranted.

**4.9.6 Conclusions on classification and labelling**

**Not Classified: conclusive but not sufficient for classification**

#### 4.10 Carcinogenicity

**Table 18: Summary table of relevant carcinogenicity studies**

| Method   | Dose levels                             | Observations and remarks<br>(effects of major toxicological significance)   |

a) Dow: studies necropsied Dec-2001- May 2001 (50 males/control), plus one study completed May 2007 and Notifier confirmed there were no multiple hepatocellular tumours in 50 male control mice).

a2) Dow: information from studies conducted between 2007 and 2012.

b) HCD in the CrI:CD1 mouse published by Charles River Labs (published paper M Gilkins and C. Clifford, March 2010): 13 studies initiated between 2002 – 2006. Includes studies of 78-104 weeks in duration (50-110 animals/study). An incidence of hepatocellular carcinoma of 6/60(10%) and 9/60 (15%) was observed in two 78 week studies. .

#### 4.10.1 Non-human information

##### 4.10.1.1 Carcinogenicity: oral

Information is available from a carcinogenicity study in rats and mice.

###### Rats

In the rat study, neoplastic changes were observed in the haematopoietic/lymphoid system, liver, thyroid, and adrenals. These are discussed individually below:

###### *Haematopoietic/lymphoid system*

Males receiving 100 (28/50) or 1000 (29/50) mg/kg bw/day had slightly higher incidence of large granular lymphocyte (LGL Fischer rat) leukaemia<sup>2</sup> than in the controls (20/50). These increases were not statistically significant and there was no evidence for an early onset of LGL leukaemia in rats exposed to pyroxsulam (Stebbins and Brooks, 2008).

###### *Historical control information*

The incidence in the top two dose groups in males was outside the historical control range of dietary or oral gavage toxicity studies performed in this laboratory both contemporaneously (studies initiated: 2002-2005) and in the past (studies initiated: 1992-1995). However, the control incidence was also higher or equal to that of the historical controls too.

The incidence did fall within the NTP pre-1995 historical control range (32-74%), and was just outside the NTP post-1995 historical control range (30 to 54% based on 5 dietary studies). These historical control ranges suggest this type of tumour has a high spontaneous rate in Fischer rats. In addition, it is possible the diet may also influence tumour incidence with a higher top range observed with the pre-1995 diet (which was similar to the diet used in this study) than with the post-1995 diet (lower protein and higher fibre). However, on its own this assertion is not conclusive and since the incidence in the top two treatment groups was higher than both the concurrent controls and laboratory historical control data the tumours cannot be dismissed on this basis alone.

###### *Dose response considerations*

The incidence of LGL leukaemia in the 100 and 1000 mg/kg bw/day dose groups was similar. This was somewhat surprising given that the high dose group was ten times that of the mid dose group. Failure to see a dose-related increase in tumour incidence raises doubt that the tumours are treatment related.

###### *Information from the repeated dose studies on the target organs*

No substance-related increase in white blood cell count or substance-related changes in differential white blood count in male rats was observed. Nor was there any histological evidence that lymphoid tissues/organs were a target organ for pyroxsulam.

---

<sup>2</sup> Other names for this type of leukaemia include: mononuclear cell leukaemia; Fischer rat leukaemia and monocytic leukaemia.

### *Conclusion*

Overall, an increase in the incidence of LGL leukaemia was observed at the top two doses in one sex (males). However, since, the control values were at the top of the historical control range; this is a relatively common tumour in Fischer rats; the increase was not statistically significant, the incidence was similar at both mid and high dose even though there was a 10-fold difference in dose level; and there was no evidence from repeated dose studies of effects in relevant organs (e.g. white blood cells, spleen liver, lungs, thymus, lymph glands), the increase in tumour incidence is not considered treatment related.

### ***Additional tumour types in rat not summarised in the table:***

#### ***Liver***

A slight increase in the incidence of hepatocellular adenomas was observed in males treated with 1000 mg/kg bw/day (1/50, 3/50, 3/50 and 4/50 in controls to high dose). This increase was within the historical control ranges for dietary or oral gavage toxicity studies performed contemporaneously in this laboratory (Historical control range: 1-6 hepatocellular adenomas) and therefore was not considered treatment related. No increase was noted in females.

#### ***Thyroid***

A slight increase in the incidence of parafollicular cell adenomas was observed in females treated with 1000 mg/kg bw/day (2/50, 2/10, 2/12 and 7/49 in controls to high dose). This increase was within the historical control range for dietary or oral gavage toxicity studies performed contemporaneously in this laboratory (Historical control range: 2-9 parafollicular cell adenomas) and therefore was not considered treatment related. No increase was noted in males.

#### ***Adrenals***

There was a slight increase in the incidence of benign pheochromocytoma in males at 1000 mg/kg bw/day (4/50, 2/20, 2/24 and 9/50 in the controls to high dose). This increase was slightly higher than the historical control range (historical control range: 3-7), but there was no increased incidence observed in females and no increase in the incidence of the malignant form of the tumour. It should also be noted the incidence for control males in a study terminated in 2007 (within two years of this study) was 7/50, which is close to the incidence observed in the high dose males of this study. Hence, overall the incidence of benign pheochromocytoma is not considered treatment related.

Overall, in rats there were no neoplastic findings considered relevant to human health.

#### **Mice**

In the CD-1 mouse study, an increase in hepatocellular adenoma incidence was observed in males at all doses compared to the controls. There was also an increase in the incidence of carcinomas observed in top dose males.

The increased incidence in hepatocellular adenomas in males was not statistically significant nor dose-related, but did slightly exceed the laboratory historical control (2-9; Dec 2001-May 2004 and 4-12; 2007-2012) in both the low dose (13/50 - 26%) and high dose (14/50 - 28%) males, but not the mid dose group (9/50 - 18%). The incidence also slightly exceeded the historical control range in the Charles River historical control database (1.4-20%; from studies initiated between 2002 and 2006). The study also showed that many of the affected males had multiple hepatic tumours. Multiple tumours are relatively rare in this strain of mouse; however, as they were also noted in control animals they are not considered treatment related, but do suggest these animals were

particularly susceptible to developing liver tumours. No increase in the incidence of adenomas in female mice was observed in this study (hepatocellular incidence of adenomas: 3 (control), 1 (low dose), 0 (mid dose), 1 (high dose)).

A slight increase in the incidence of hepatocellular carcinoma was noted at the limit dose in males (4/50 (8%) compared to 1/50 (2%) in the contemporary control). No carcinomas were noted in females. The increase in male carcinoma incidence at the top dose was higher than either of the laboratory historical control ranges (0/50 - 2/50 (0-4%)), but was within the historical control range available for Charles River Labs where the incidence of hepatocellular hypertrophy from 13 studies conducted between 2002 and 2006 ranged from 0-15% (including an incidence of 6/60(10%) and 9/60(15%) in two 78 week studies). See tables 18a and 18b for further information on historical controls.

#### **4.10.1.2 Carcinogenicity: inhalation**

No information available

#### **4.10.1.3 Carcinogenicity: dermal**

No information available

#### **4.10.2 Human information**

No information available

#### **4.10.3 Other relevant information**

Not applicable.

#### **4.10.4 Summary and discussion of carcinogenicity**

The carcinogenicity of pyroxsulam has been investigated in rats (Fischer 344) and mice (CD-1).

No treatment-related carcinogenic effects were observed in rats.

In the mouse, the incidence of liver adenomas and carcinomas was slightly higher than the contemporaneous and laboratory historical control in males, but the carcinomas were within the control range provided for Charles River Labs. In addition, whilst the incidence of adenomas was increased at the low and top dose groups, it was within the laboratory historical control range in the mid dose group. Further, these findings occurred in male mice only, which appeared to be susceptible to liver tumour formation with multiple adenomas (rather than single incidences) observed in the livers of both control and treated animals. In conclusion, it is considered that there is insufficient evidence in this study to conclude a treatment-related carcinogenic effect of pyroxsulam.

#### **4.10.5 Comparison with criteria**

As there is insufficient evidence for a carcinogenic effect in rats and mice, and there are no other concerns about the potential carcinogenicity of pyroxsulam, no classification is proposed.

## 4.11 Toxicity for reproduction

### 4.11.1 Effects on fertility

**Table 19: Summary table of relevant reproductive toxicity studies - Fertility**

| Method  | Dose levels  | Observations and remarks<br>(effects of major toxicological significance)   |
|---|--|---|
| Two-generation study<br>OECD 416 (2001) – deviation: no functional investigation of pups and no examination of reproductive tissues of weanlings<br>GLP<br>Oral(dietary)<br>27 Sprague-Dawley rats/sex/dose<br>Carney, Zablony, Stebbins (2005) | Males<br>P1 generation – 0, 106, 321 and 1078 mg/kg bw/day<br>P2-generation – 112, 344 and 1138 mg/kg bw/day<br>Females<br>P1 generation – 104, 311, 1043 mg/kg bw/day<br>P2 generation – 104, 316 and 1049 mg/kg bw/day | Parental toxicity<br>Parental toxicity was limited to a very low incidence of perineal staining in the 300 mg/kg bw/day and 1000 mg/kg bw/day dose groups – this effect was not considered adverse.<br>Erosion of the stomach was observed in P1 females treated with 300 mg/kg bw/day and 3 at 1000 mg/kg bw/day. The extent of the finding was very slight. The effects were not considered treatment related as not observed in the P2 animals.<br>Reproductive toxicity<br>No effects of treatment on mating, conception, fertility or gestation indices, post-implantation loss, time to mating, or gestation length in either generation<br>Offspring effects<br>1000 mg/kg bw/day<br>A small non-statistically significant decrease in pup weight in F1 males and females on day 21 (circa. 1 g) and F1 and F2 males on day 22 (circa 2-3g). When the individual pup weights considered, the difference did not appear biologically significant.<br>A NOAEL for parental, reproductive and offspring effects of 1000 mg/kg bw/day was derived. |

#### 4.11.1.1 Non-human information

Information on reproductive toxicity is available from a 2-generation study in Sprague-Dawley rats.

In the study no adverse effects on reproductive toxicity was observed. The only effect on offspring observed was slightly reduced bodyweight. However, when the individual weights of the pups were considered, the difference did not appear to be biologically significant. Overall, the results suggest pyroxsulam does not affect fertility or reproductive performance.

#### 4.11.1.2 Human information

No information available.

#### 4.11.2 Developmental toxicity

**Table 20: Summary table of relevant reproductive toxicity studies - Development**

| Method   | Dose levels   | Observations and remarks<br>(effects of major toxicological significance)   |
|--|---|---|
| Developmental toxicity<br>OECD 414 (2001) – dosing started on day 6<br>GLP<br>26 female Sprague-Dawley rats/dose<br>Oral gavage<br>Slotter (2005a) | 0, 100, 300 or 1000 mg/kg bw/day from day 6 to day 20<br>Vehicle – 0.5% methylcellulose   | Maternal toxicity<br>No maternal toxicity was observed<br>Fetal examination<br>The incidence of testicular alterations was slightly increased at 1000 mg/kg bw/day compared to controls (concurrent and historical).<br>The observations were observed in three litters: <ul style="list-style-type: none"> <li>• Missing testes (malformation) in one foetus from one litter;</li> <li>• Hypoplastic testis (malformation) in one foetus from another litter</li> <li>• Cystic testis (variation) in three fetuses from another litter</li> </ul> In addition, one foetus from the 300 mg/kg bw/day also had a missing testis.<br>A NOAEL for maternal and Foetal toxicity of 1000 mg/kg bw/day was derived.   |
| Developmental toxicity study<br>OECD 414 (2001)<br>GLP<br>Oral gavage<br>26 New Zealand White rabbits<br>Slotter (2005b)                           | 0, 30, 100 and 300 mg/kg bw/day in 0.5% methylcellulose – doses based on the results of a preliminary study, in which slight toxicity was observed at 300 mg/kg bw/day (decreased faecal output, mean body weight and food consumption) | Maternal toxicity<br>One female from each treatment group died – these deaths were not considered treatment related.<br>No treatment-related effects on bodyweight were observed at any dose level.<br>Transient ↓ in food consumption at 300 mg/kg bw/day<br>Foetal examination<br>Absence of small gall bladder was observed in several foetuses from treated groups (3.5%, 2.9, 2.8% of fetuses per litter, low to high dose), but not in the controls. Since the % affected foetuses per litter only exceeded the historical control range (0.8%; 0-3%) at the lowest dose, the effect is not considered treatment related.<br>Slight increases in the incidence of a few skeletal variations were noted, principally in the top dose group, but these were not statistically significant and were either well within the historical control range or showed no clear effect in terms of total foetal or litter incidence.<br>No testicular effects were observed.<br>A NOAEL of 300 mg/kg bw/day for maternal and foetal toxicity was derived. |

##### 4.11.2.1 Non-human information

Information is available from developmental toxicity studies in rat and rabbit.

In the rat study, conducted up to 1000 mg/kg bw/day, the only effects of concern were in the testes (see table for details). These effects were dismissed by the study authors on the basis of their low incidence and the fact that similar effects were not noted in the 2-generation study conducted at equivalent doses (although the 2-generation study was a dietary study whereas the developmental study was via oral gavage). In addition, the applicants also provided additional arguments to support their opinion why they were not substance related.

- 1) "...compounds known to produce hypoplastic testis and/or missing testis are androgen receptor antagonists or endocrine active agents (Foster and Harris, 2005; Carruthers and Foster, 2005; Anway et al, 2005). These compounds have been shown to interfere with the development of the male reproductive tract, embryonic testis development and male fertility. Male fertility in these particular studies was measured by different parameters (e.g. sperm mobility, sperm counts, testis and epididymal weights, anogenital distance). Pyroxsulam had no effect on any of these parameters; this lack of correlation is another piece of the supportive data to consider these findings in the rat developmental study as not treatment related".
- 2) Reproductive alterations are rarely observed in isolation, but instead individual pups and multiple pups, within a litter, will have a suite of treatment-related effects (Foster and Harris, 2005, Carruthers ND Foster, 2005). In addition, for pyroxsulam, the absence of less serious effects that would be expected to precede the more serious effects of missing or hypoplastic testes was noted (reference to Bay, 2006). In particular, Rasoulpour proposes that cryptorchism, hypospadias and decreased testes and accessory organ weight and sperm counts would occur long before any treatment-induced missing or hypoplastic testes.
- 3) Testis cysts (clear sacs with a bubble like appearance) are incidental observations and not related to the hypoplastic or missing testes. This conclusion was based on data mining (no reference to similar testis cysts on normal or treated rats was found) and consultation with US and European test laboratories (most laboratories do not record these cysts). The consensus of the reproductive toxicologists consulted was that because the effect occurred in three pups from one litter it was an incidental finding.

Given the low incidence of the effects observed at the limit dose (1000 mg/kg bw/day), the absence of associated findings and the fact that similar findings were not observed in the 2-generation study or the rabbit developmental study, the effects are considered spontaneous and not treatment related. Overall, the results suggest that pyroxsulam does not cause developmental toxicity in rats.

In the rabbit developmental toxicity study, no significant maternal toxicity or evidence of treatment related effects were observed, suggesting pyroxsulam is not a developmental toxicant in rabbits.

#### **4.11.2.2 Human information**

No information available

#### **4.11.3 Other relevant information**

Not applicable

#### **4.11.4 Summary and discussion of reproductive toxicity**

Effects on fertility were investigated in a two-generation study in rats. In the study no adverse effects on reproductive toxicity was observed up to a dose of 1000 mg/kg bw/day. The only effect on offspring observed was slightly reduced bodyweight. However, when the individual weights of the pups were considered, the difference did not appear to be biologically significant. Overall, the results suggest pyroxsulam does not affect fertility or reproductive performance.

The developmental toxicity of pyroxsulam has been investigated in a developmental toxicity study in rats and rabbits. In rats, the only effects were testicular effects (missing testes, hypoplastic testes) in offspring. However, given the low incidence, the lack of related effects and failure to see similar

effects in the 2-generation study or the rabbit developmental study, these findings were not considered treatment related. In rabbits, no malformations of concern were observed. Overall, there was no evidence of a direct adverse effect on development.

**4.11.5 Comparison with criteria**

No effects were observed that provide sufficient evidence to cause a strong suspicion of impaired fertility or developmental toxicity.

**4.11.6 Conclusions on classification and labelling**

**Not Classified: conclusive but not sufficient for classification**

**4.12 Other effects**

**4.12.1 Non-human information**

**4.12.1.1 Neurotoxicity**

| Method   | Dose Levels                      | Observations and Remarks   | Reference                                 |
|--|----------------------------------|--|---|
| Chronic neurotoxicity study (one-year)<br><br>OECD 424 (1997)<br>GLP<br><br>Dietary exposure<br><br>10 Fischer 344 rats/sex/dose | 0, 10, 100 and 1000 mg/kg bw/day | 4.4% ↓ bodyweight (based on all animals in this combined chronic/carcinogenicity and neurotoxicity study) was slightly reduced in females.<br><br>Increased perineal staining in females and limited evidence of this effect in males<br><br>There were no substance related effects on FOB findings or motor activity.<br><br>There were no macroscopic or microscopic effects observed in the central or peripheral nervous systems.<br><br>A NOAEL of 1000 mg/kg bw/day was derived for neurotoxicity | Maurissen, Andrus, Yano and Brooks (2005) |

In a one-year neurotoxicity study in rats, there were no neuropathological findings in the central and peripheral nervous systems or any effects in the functional observation battery or on motor activity suggestive of neurotoxicity. Overall, pyroxsulam does not appear to be neurotoxic.

**4.12.1.2 Immunotoxicity**

No information available

Not applicable

**4.12.1.4 Human information**

**4.12.2 Summary and discussion**

No neurotoxic effects were observed in a one year neurotoxicity study in rats up to a dose of 1000 mg/kg bw/day (Maurissen *et al*, 2005).

**4.12.3 Comparison with criteria**

No neurotoxic effects were observed in a one year neurotoxicity study in rats up to a dose of 1000 mg/kg bw/day (Maurissen *et al*, 2005).

**4.12.4 Conclusions on classification and labelling**

**Not Classified: conclusive but not sufficient for classification**

## 5 ENVIRONMENTAL HAZARD ASSESSMENT

Pyroxsulam (referred to in test reports as XDE-742) is a systemic post-emergence herbicide used for weed control. It is absorbed by foliage but also plant roots. Available environmental fate and hazard studies have been considered under Directive 91/414/EEC (subsequently replaced by EU Regulation 1107/2009) and summarised in the Draft Assessment Report, 2012 and subsequent DAR Addenda (Volume 3, B8; Environmental Fate and Behaviour and Volume 3, B9: Ecotoxicology). The agreed endpoints from the peer review of pyroxsulam under Directive 91/414/EEC are also included in the 2013 EFSA Conclusion.

The key information pertinent to determining a classification is presented below. All radiolabelled studies used  $^{14}\text{C}$ -pyroxsulam with a purity of >97% and up to two labels as shown in Figure 1.

**Figure 1: Structure of pyroxsulam indicating positions of the  $^{14}\text{C}$  labels.**

PY = 2- and 6- positions of pyridine ring  
TP = 2-position of triazolopyrimidine ring

Pyroxsulam has a measured dissociation constant of 4.67 at 20°C (Cathie, 2004). It is anticipated pyroxsulam will exist in its dissociated form at environmentally relevant pH (e.g. estimated 17.5% ionized at pH 4, 68% ionised at pH 5, 95.5% ionised at pH 6, and 99.5% ionised at pH 7).

Where available information on degradation products is included – full details of degradant names and structures are presented in Annex I.

## 5.1 Degradation

A summary of available valid information on the fate of pyroxsulam is presented in Table 21 below.

**Table 21: Summary of relevant information on degradation**

### 5.1.1 Stability

#### *Aqueous hydrolysis*

An aqueous hydrolysis study (Yoder, 2004) is available following GLP, US EPA Guideline Subdivision N, Series 161-1 and SETAC Guideline part 1, section 9. The study used <sup>14</sup>C radio labelled pyroxsulam (0.1 mg a.s./l). Test solutions were incubated at 20 °C in the dark for 32 days. No significant degradation was observed and analysis showed 100% radioactivity as pyroxsulam at study termination. On this basis, pyroxsulam is considered hydrolytically stable.

#### *Aqueous photolysis*

An aqueous photolysis study (Byrne *et al*, 2006) is available following GLP, US EPA Guideline Subdivision N, Series 161-2 and SETAC Guideline part 1, section 10.1. The study used <sup>14</sup>C radio labelled pyroxsulam (1.0 mg a.s./l). Test solutions were incubated at pH 7 for 15 days at 20 °C under constant irradiation using a xenon lamp (wavelengths below 290 nm filtered out). This is considered equivalent to 73.5 days of non-continuous irradiation in summer sun at 40°N.

The quantum yield of pyroxsulam was determined using an actinometer to be 4.41 x10<sup>-1</sup>. This results in a predicted DT<sub>50</sub> of 3.2 days at 40°N in summer sunlight. Correcting for lamp intensity, the experimental DT<sub>50</sub> for pyroxsulam at 40°N in summer sunlight was 4.1 days.

Photodegradation is considered to occur through cleavage of the sulphonamide bridge resulting in the degradants pyridine sulfinic acid and ADTP. The DT<sub>50</sub> of pyridine sulfinic acid was determined to be 32 days at 40°N in summer sunlight. The DT<sub>50</sub> of ADTP was determined to be 32-41 days at 40°N in summer sunlight.

## 5.1.2 Biodegradation

### 5.1.2.1 Biodegradation estimation

Not available

### 5.1.2.2 Screening tests

A ready biodegradation study (Schwarz, 2003) is available following OECD Guideline 301B (CO<sub>2</sub> Evolution) and GLP using pyroxsulam. Activated sludge from a laboratory wastewater plant treating municipal sewage was used at 30 mg/l with 52 mg test item. Validation criteria for the Reference and Toxicity Controls were met. Ultimate biodegradation reached a maximum of 19 and 23% in the duplicate samples over 28 days. Overall, the substance is considered not readily biodegradable.

### 5.1.2.3 Simulation tests

A distribution and degradation in aerobic water-sediment system study (Yoder *et al*, 2006c) is available following SETAC Guideline (Part 1, section 8.2) and BBA Guideline (Part IV, section 5-1). The study used <sup>14</sup>C-pyroxsulam with two labels. Two aerobic systems were used: 'UK' and 'France'. The water and sediment test conditions are included in Table 22 below. The system was treated with 0.016 mg pyroxsulam per litre of water via the water surface.

**Table 22: Water-sediment system test conditions**

| Criteria                   | River Roding, UK   | Haut Languedoc, France   |
|----------------------------|--|--|
| <b>Water properties</b>    | pH: 8.3<br>Dissolved organic carbon: 4.8 ppm<br>Oxygen: 0.2 mg/l at start to 2.1 mg/l at end<br>Redox potential: 125.9 mV at start to 22.4 mV at end | pH: 8.1<br>Dissolved organic carbon: 5.8 ppm<br>Oxygen: 5.0 mg/l at start to 2.0 mg/l at end<br>Redox potential: 228.4 mV at start to 20.8 mV at end |
| <b>Sediment properties</b> | 46% sand; 26% silt; 28% clay<br>Organic carbon 2.2% at start<br>pH: 7.3<br>Redox potential: -177.3mV at start to -149.2 mV at end                    | 88% sand; 10% silt; 2% clay<br>Organic carbon 2.9% at start<br>pH: 4.8<br>Redox potential: -74.1 mV at start to -72.0 mV at end                      |

The study was conducted at 20 °C, in the dark under aerobic conditions for up to 101 days.

Radioactivity was determined by Liquid Scintillation Counting (LSC) and subsequent analysis by High Performance Liquid Chromatography (HPLC) was undertaken. Total mean recoveries for both systems were >90% Applied Radioactivity (AR) for both labels at each sampling point.

Pyroxsulam dissipated from the water phase to the sediment phase in both systems where degradation to 7-OH-XDE-742 and ATSA occurred (Figure 2 shows the proposed aerobic degradation pathway). A third degradant was observed at >10% AR (max. 16.5% AR) but was unable to be identified. Further investigation was unable to recreate the compound and it was concluded that it was an experimental anomaly.

In water pyroxsulam decreased from initial 84-103.4% AR to 14.4-22.1% AR on day 101. In sediment pyroxsulam increased from initial 0.8-16.1% AR to peak between 17.2 and 42% AR by day 75.

A Single First Order (SFO) kinetics approach was applied to calculated DT<sub>50</sub> values. The study authors removed outliers and refitted the model to improve fit. While this approach was not statistically justified, overall slower rates were derived and the approach was accepted in the DAR.

Whole system dissipation DT<sub>50</sub> values for both labels were as follows:

Pyroxsulam DT<sub>50</sub> whole system: 24 days for UK system and 12 days for France system  
 7-OH-XDE-472 DT<sub>50</sub> whole system: 16 days for UK system and 42 days for France system  
 ATSA DT<sub>50</sub> whole system: 22 days for UK system and 71 days for France system

Minimal mineralisation was observed with a maximum of 2% AR in UK system and 0.8% AR in France system after 101 days.

**Figure 2: Proposed degradation pathway of pyroxsulam in water-sediment systems under aerobic conditions (taken from DAR, Volume 3, Annex B8: Environmental Fate and Behaviour – January 2012)**

### 5.1.3 Summary and discussion of degradation

Pyroxsulam is considered hydrolytically stable.

Pyroxsulam is susceptible to photodegradation. The experimental DT<sub>50</sub> in sterile pure water was 4.1 days at 40°N in summer sunlight. Two degradants were identified with DT<sub>50</sub> values of 32 and 21-41 days 40°N in summer sunlight. The actual degree of photodegradation in the aquatic environment depends on local conditions and seasons. Therefore, in reality the potential for aquatic photolysis is likely to be limited.

In a ready biodegradation study a maximum of 23% degradation was observed over 28 days and pyroxsulam is considered to be 'not readily degradable'.

In an aerobic water-sediment study pyroxsulam was observed to dissipate from the water column to sediment in two systems where subsequent decline was also noted. Estimated whole system dissipation DT<sub>50</sub> values for pyroxsulam were between 12 and 24 days. Two key degradants were observed with whole system DT<sub>50</sub> values of 16 to 42 and 22 to 71 days. Minimal mineralisation (maximum 2% AR by day 101) was observed.

Overall, the degradation information does not provide sufficient data to show pyroxsulam is ultimately degraded within 28 days (equivalent to a half-life <16 days) or transformed to non classifiable products. Consequently, pyroxsulam is considered not rapidly degradable for the purpose of classification and labelling.

## 5.2 Environmental distribution

### 5.2.1 Adsorption/Desorption

Following OECD Test Guideline 106 and GLP, a soil adsorption study (Smith, 2004) is available investigating the adsorption of pyroxsulam. The study used 10 soils from the UK and Germany and <sup>14</sup>C-pyroxsulam. Soil pH ranged from 5.4 to 7.9 and organic carbon from 0.8 to 3.8%. When normalised for organic carbon, adsorption was observed to be pH dependant with increasing adsorption with decreasing soil pH. The K<sub>oc</sub> values ranged between 3.62 and 83.86 ml/g. This equates to log K<sub>oc</sub> values between 0.56 and 1.92.

### 5.2.2 Volatilisation

Experimental data (Madsen and Kastel, 2003) indicate the vapour pressure for pyroxsulam is <1 x 10<sup>-7</sup> Pa at 20 °C following OECD Test Guideline 104. The Henry's Law Constant (Madsen, 2006b) was calculated to be <1.36 x 10<sup>-8</sup> Pa m<sup>3</sup> mol<sup>-1</sup> at 20 °C, pH 7 indicating pyroxsulam is unlikely to partition from the water phase to air.

### 5.2.3 Distribution modelling

Not relevant for classification and labelling.

### 5.3 Aquatic Bioaccumulation

**Table 23: Summary of relevant information on aquatic bioaccumulation**

| Method   | Results   | Remarks | Reference       |
|--|---|---------|-----------------|
| Partition coefficient <i>n</i> -octanol/water (shake flask method) | Log K <sub>ow</sub> 1.08 at pH 4, 20°C<br>Log K <sub>ow</sub> -1.01 at pH 7, 20°C<br>Log K <sub>ow</sub> -1.6 at pH 9, 20°C | Valid   | Turner, (2004b) |

#### 5.3.1 Aquatic bioaccumulation

##### 5.3.1.1 Bioaccumulation estimation

No data available.

##### 5.3.1.2 Measured bioaccumulation data

No data available.

#### 5.3.2 Summary and discussion of aquatic bioaccumulation

The experimental log K<sub>ow</sub> for pyroxsulam is 1.08 at pH 4 and -1.01 at pH 7 and 20°C (Turner, 2004b). The lower pH 4 value is anticipated to represent the non-ionised form while the pH 7 value is anticipated to reflect a predominantly ionised form likely to be present at environmentally relevant pH. Overall, the log K<sub>ow</sub> is below the CLP logK<sub>ow</sub> trigger value of  $\geq 4$  intended to identify substances with a potential to bioaccumulate. Given this low value, an experimental BCF study was not required.

### 5.4 Aquatic toxicity

A summary of available valid information on the aquatic toxicity of pyroxsulam (98% purity) is presented in Table 24. Where available, a summary of valid information for degradants is also included in Annex II, Table 1.

Studies were reviewed under Directive 91/414/EEC and considered valid and reliable. Further details are presented for studies conducted on the active substance pyroxsulam but not for its degradants as these are all of similar or lower toxicity and are not considered further for the environmental hazard classification of pyroxsulam.

The water solubility of pyroxsulam is pH dependant (16.4 mg/l at pH4, 3.2 g/l at pH 7 and 13.7 g/l at pH 9. The water pH during aquatic testing is noted in Table 24. Given experimental pH values, this is not anticipated to have affected key study results.

**Table 24: Summary of relevant information on aquatic toxicity for pyroxsulam (XDE-742)**

| Guideline / GLP status   | Species   | Endpoint   | Exposure  |          | Results                    |   | Reference                        |

## Notes:

mm refers to results based on mean measured test concentrations

n refers to nominal concentrations

\*formerly *Selenastrum capricornutum*

## 5.4.1 Fish

### 5.4.1.1 Short-term toxicity to fish

Two acute toxicity to fish studies using pyroxsulam (purity >98%) are available following GLP and OECD Guideline 203.

#### Study 1 (Zok, 2003c)

Using Rainbow Trout (*Oncorhynchus mykiss*), a static limit test was performed using the nominal concentration 100 mg/l. Study conditions were within the test guideline range and validation criteria were met. Analytical verification was >86% of nominal. The study 96-h LC<sub>50</sub> was >100 mg a.s./l (nominal), >87 mg a.s./l (mean measured). The study 96-h NOEC was 100 mg a.s./l (nominal), 87 mg a.s./l (mean measured).

#### Study 2 (Zok, 2003d)

Using Fathead Minnow (*Pimephales promelas*) a static limit test was performed using the nominal concentration 100 mg/l. Aside from one dissolved oxygen measurement dropping to 58% below the 60% guideline, study conditions were within the test guideline range and validation criteria were met. The study 96-h LC<sub>50</sub> was >100 mg a.s./l (nominal), >94.4 mg a.s./l (mean measured). The study 96-h NOEC was 100 mg a.s./l (nominal), 94.4 mg a.s./l (mean measured).

### 5.4.1.2 Long-term toxicity to fish

A 40-day flow-through chronic toxicity to fish study (Marino *et al*, 2005) using pyroxsulam following GLP and OECD Guideline 210 is available. The study used Fathead Minnow (*Pimephales promelas*) and the following endpoints: time to hatch, hatching success, survival and growth. The nominal exposure range was 0.778, 1.3, 2.16, 3.69, 6 and 10 mg a.s./l. Results were based on mean measured values: 0.836, 1.28, 2.23, 3.62, 6.11 and 10.1 mg a.s./l. Validity criteria were met and the test is considered reliable. Significant effects were not observed for any parameter. The study 40-d NOEC was 10.1 mg a.s./l reflecting the highest mean measured exposure concentration.

## 5.4.2 Aquatic invertebrates

### 5.4.2.1 Short-term toxicity to aquatic invertebrates

A static acute toxicity to *Daphnia magna* study (Marino *et al*, 2004) using pyroxsulam is available following GLP and OECD Guideline 202. The nominal exposure range was 13, 21.6, 36, 60 and 100 mg a.s./l. Results were based on mean measured values: 12.2, 20.6, 34.9, 58.8 and 100 mg a.s./l. Validity criteria were met and the test is considered reliable. As no significant effects were observed, the study 48-h LC<sub>50</sub> was >100 mg a.s./l based on mean measured. The study 48-h NOEC was 100 mg a.s./l based on mean measured.

### 5.4.2.2 Long-term toxicity to aquatic invertebrates

A semi-static chronic toxicity to *Daphnia magna* study (Marino *et al*, 2005) using pyroxsulam is available following GLP and OECD Guideline 211. The study assessed the following endpoints: survival, reproduction, length and weight. The nominal exposure range was 0.0313, 0.625, 1.25, 2.5, 5 and 10 mg a.s./l. Results were based on mean measured values: 0.0353, 0.701, 1.37, 2.66, 5.27 and 10.4 mg a.s./l. Validity criteria were met and the test is considered reliable. Significant effects were not observed for any parameter. The study 21-d NOEC was 10.4 mg a.s./l reflecting the highest mean measured exposure concentration.

## 5.4.3 Algae and aquatic plants

### *Algae:*

Four algal growth inhibition studies using pyroxsulam are available.

#### Study 1 (Hancock *et al*, 2004)

A static algal growth inhibition test using pyroxsulam (purity 98%) and *Pseudokirchneriella subcapitata* is available following GLP and OECD Guideline 201. The nominal exposure range was 0.0313, 0.0625, 0.125, 0.25, 0.5, 1 and 2 mg a.s./l. Results were based on mean measured values: 0.0261, 0.0550, 0.126, 0.252, 0.503, 1.01 and 2.04 mg a.s./l. Validity criteria were met and the test is considered reliable. The 72-h E<sub>r</sub>C<sub>50</sub> was 0.924 mg a.s./l and the 72-hour NOE<sub>r</sub>C was 0.055 mg a.s./l based on mean measured concentrations.

#### Study 2 (Hoberg *et al*, 2005a)

A static algal growth inhibition test using pyroxsulam (purity 98%) and the cyanobacteria *Anabaena flos-aquae* is available following GLP and OECD Guideline 201. The nominal exposure range was 0.041, 1.0, 2.6, 6.4, 16, 40 and 100 mg a.s./l. Results were based on mean measured values: 0.036, 0.89, 2.2, 5.4, 13, 28 and 85 mg a.s./l. Validity criteria were met and the test is considered reliable. Initial pH values were 5 to 7.4 and final pH values 5.1 to 7.6. Study observations did not include undissolved material and the lower range pH is not anticipated to have affected study results. The 72-h E<sub>r</sub>C<sub>50</sub> was 41 mg a.s./l and the 72-hour NOE<sub>r</sub>C was 13 mg a.s./l based on mean measured concentrations.

#### Study 3 (Hancock *et al*, 2005)

A static algal growth inhibition test using pyroxsulam (purity 98%) and diatom *Skeletonema costatum* is available following GLP and OECD Guideline 201. The nominal exposure range was 3.13, 6.25, 12.5, 25, 50 and 100 mg a.s./l. Results were based on mean measured values: 3.4, 6.8, 13.6, 26.7, 52.8 and 105 mg a.s./l. Validity criteria were met and the test is considered reliable. The

96-h  $E_rC_{50}$  was 59 mg a.s./l and the 96-hour  $NOE_rC$  was 3.4 mg a.s./l based on mean measured concentrations.

#### Study 4 (Hoberg, 2005b)

A static algal growth inhibition test using pyroxsulam (purity 98%) and *Navicula pelliculosa* is available following GLP and OECD Guideline 201. The nominal exposure range was 0.1, 0.26, 0.64, 1.6, 4 and 10 mg a.s./l. Results were based on mean measured values: 0.1, 0.29, 0.67, 1.7, 4 and 10 mg a.s./l. Validity criteria were met and the test is considered reliable. The 72-h  $E_rC_{50}$  was 6.9 mg a.s./l and the 72-hour  $NOE_rC$  was 4 mg a.s./l based on mean measured concentrations.

#### *Aquatic plants:*

A semi-static 7-day toxicity to *Lemna gibba* study (Hancock *et al*, 2005b) using pyroxsulam is available following GLP and OECD Guideline 221.

Exposure solutions were prepared with the aid of the solvent DMF (0.1ml/l) and a solvent control was included. The nominal exposure range was 0.313, 0.625, 1.25, 2.5, 5 and 10  $\mu$ g a.s./l. Analytical measurement used liquid chromatography positive electrospray ionization mass spectrometry (LC/PESI-MS). Results were based on mean measured fresh media concentrations from days 0, 3 and 5 as pyroxsulam was considered stable based on analytical concentrations of expired solutions which were 89.5 to 117% nominal. This resulted in a mean measured test concentration range of: 0.335, 0.681, 1.34, 2.81, 5.23 and 10.3  $\mu$ g/l.

The study pH was 7.5 – 7.9 initially and 7.1 – 8.3 for expired solutions with plants. Validity criteria were met and the test is considered reliable. The study endpoints were percentage reduction in frond number, biomass, growth rate based on frond number and growth rate based on biomass. Table 25 shows growth rates in relation to exposure concentrations. Table 26 shows effect concentrations and NOEC values for assessed endpoints.

**Table 25: Summary of pyroxsulam (XDE-742) effects on growth rate of the aquatic plant, *Lemna gibba***

| Mean Measured Concentration ( $\mu$ g a.s./L) | Mean growth rate per day | % Difference <sup>a</sup> |
|---|--------------------------|---------------------------|
| Control                                       | 0.404                    | ---                       |
| Vehicle Control                               | 0.393                    | ---                       |
| Pooled Control                                | 0.398                    | ---                       |
| 0.335   | 0.411                    | -3                        |
| 0.681   | 0.405                    | -2                        |
| 1.34  | 0.376*                   | 5                         |
| 2.81  | 0.249*                   | 37                        |
| 5.23  | 0.131*                   | 67                        |
| 10.3  | 0.0844*                  | 79                        |

<sup>a</sup> Percent difference as compared to the pooled control was determined on day 7

\* Growth was significantly less than the pooled control (Dunnett's test,  $p = 0.05$ ).

**Table 26: Summary of pyroxsulam (XDE-742) effect concentrations for the aquatic plant, *Lemna gibba* - based on mean measured test concentrations over 7 days exposure**

| Endpoint              | Parameter Effect Concentration as µg a.s./L |                      |       |
|-----------------------|---|----------------------|-------|
|                       | EC <sub>50</sub>                            | 95% confidence limit | NOEC  |
| FronD Number          | 2.57  | 1.16 - 5.70          | 0.681 |
| Growth Rate           | 3.88  | 1.68 - 8.97          | 0.681 |
| Biomass as Dry Weight | 3.82  | 2.23 - 6.56          | 0.681 |

The key growth rate endpoint for acute hazard classification purposes is the 7-d E<sub>r</sub>C<sub>50</sub> of 0.00388 mg a.s./l (95% confidence intervals 0.00168 to 0.00897 mg a.s./l) based on mean measured. The key growth rate endpoint for chronic classification is the 7-d NOE<sub>r</sub>C of 0.000681 mg a.s./l, also based on mean measured test concentrations.

#### 5.4.4 Other aquatic organisms (including sediment)

A static 28-day toxicity to *Chironomus riparius* (midge larvae) study (Henry *et al*, 2005) is available using pyroxsulam (98% purity) following OECD Guideline 219. The nominal exposure range was 6.25, 12.5, 25, 50 and 100 mg a.s./l. Exposure was via the water phase and a sediment phase was present. Concentrations of pyroxsulam (as a percentage of nominal) in the water phase were 104% on day 0, 86.3% on day 7 and 99% on day 28. Validity criteria were met and the test is considered reliable. No statistical differences were observed between exposure and control systems. The 28-day NOEC was 100 mg a.s./l based on nominal.

#### 5.5 Comparison with criteria for environmental hazards (sections 5.1 – 5.4)

For the purpose of classification, pyroxsulam is considered not rapidly degradable.

The experimental log K<sub>ow</sub> for pyroxsulam is 1.08 at pH 4 and -1.01 at pH 7 and 20°C. The lower pH 4 value is anticipated to represent the non-ionised form while the pH 7 value is anticipated to reflect a predominantly ionised form likely to be present at environmentally relevant pH. Overall, the log K<sub>ow</sub> is considered to be below the CLP log K<sub>ow</sub> trigger value of ≥ 4 intended to identify substances with a potential to bioaccumulate.

Identified degradants are of similar or lower toxicity to the parent substance (see Annex II) and are not considered further for the environmental classification of pyroxsulam.

Aquatic acute toxicity data on pyroxsulam are available for fish, invertebrates, algae and aquatic plants. Aquatic plants are the most acutely sensitive trophic group. The lowest L(E)C<sub>50</sub> value is a 7-day E<sub>r</sub>C<sub>50</sub> of 0.00388 mg/l for *Lemna minor* in the range 0.001 to ≤0.01 mg/l. On this basis pyroxsulam should be classified as Aquatic Acute 1 with an M factor of 100.

Adequate chronic toxicity data on pyroxsulam are available for fish, invertebrates, algae and aquatic plants. The lowest value is a 7-day NOE<sub>r</sub>C for *Lemna minor* of 0.0007 mg/l. Given this is in the range 0.0001 to ≤0.001 mg/l and the substance is considered non-rapidly degradable, pyroxsulam should be classified as Aquatic Chronic 1 with an M factor of 100.

**5.6 Conclusions on classification and labelling for environmental hazards (sections 5.1 – 5.4)**

**Aquatic Acute 1; H400: Very toxic to aquatic life**

**Acute M factor = 100**

**Aquatic Chronic 1; H410: Very toxic to aquatic life with long lasting effects**

**Chronic M factor = 100**
